Young, Hon. Robert A., Congressman from Missouri; statement 1146

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

WEDNESDAY, JULY 20, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 10:08 a.m., in room 2167, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Also present: Mr. Young of Missouri.

Mr. Levitas. The subcommittee will please come to order.

This morning the Subcommittee on Investigations and Oversight of the Committee on Public Works and Transportation continues with the second phase of its inquiry into the matter of hazardous waste contamination of the Nation's water resources.

As I mentioned, as we started this second phase of our hearing several weeks ago in the aftermath of the confrontation with the executive branch and Environmental Protection Agency over the documents that had been denied this committee, those documents having now been made available and rather substantial changes made in personnel at EPA, we resume with the assistance of the documents that were originally denied an investigation that was contemplated well over a year ago into the program itself.

We view these hearings as partaking of a Janus-like quality, the Roman god of two heads, both looking to the past to see what has happened; but more importantly, looking to the future to see what can be done as we deal with this matter to protect the people, the citizens of this Nation from the impact of and consequences of hazardous waste.

Today's session, and those scheduled for tomorrow and Tuesday and Wednesday of next week, will focus on the health and economic damages experienced by people exposed to toxic chemical waste and problems associated with their efforts to obtain full compensation for those damages, the so-called victim compensation issue.

The issue of victim compensation when reduced to its basic components is also a question of risk assessment: What level of risk do we, as a Nation, believe is appropriate when it comes to exposing human populations to the uncertainties of hazardous waste, or for that matter any toxic chemical? When that level of risk is exceeded, what mechanisms or remedies should be available to compensate those who have been injured as a result of that exposure?

The Superfund law, when enacted in 1980, answered that question so far as it concerned the cleanup of an abandoned hazardous waste site. All that is required at a minimum is, and I quote, a "substantial threat which may present an imminent and substantial danger to the public health and welfare." Similarly, the law provides for assessment of damages against the responsible party, again quoting, "for injury to, destruction of, or loss of natural resources." But the law does not provide for such compensation for injury or damages to individuals, whether such damage is to their health or their economic well-being.

Those who believe that such a provision was necessary did not prevail during the debates that led to the enactment of the Superfund statute and, in large part, this was due to the controversy and uncertainties as to the need for such a provision. Some people have argued and continue to argue there is not enough evidence to justify changes in Federal law. That there is not enough evidence to show with absolute certainty that exposure to hazardous waste cause health or other adverse effects. Yet there would seem to be considerable evidence to the contrary offered by others.

Over the past several years we have seen national health and financial problems faced by residents of Love Canal were not unique, nor were they an aberration. One has simply to look at the problems faced by those exposed to hundreds of tons of DDT in Triana, AL, or those who unknowingly made their homes on the asbestos tailings of Globe, AZ, or the events following the disclosure of high levels of dioxin at Times Beach, MO, a community we will hear more about today.

As my colleague, Congressman Molinari, has frequently pointed out, almost every day when we pick up a newspaper we find the disclosure of another hazardous wastesite that is jeopardizing the health, or potentially jeopardizing the health of the American people. I suppose it is ironic that this morning when I received a copy of the Atlanta Constitution, the morning paper in Atlanta, the banner headline of today's newspaper reads "EPA Seals Site of Atlanta Plant," and the article goes on to discuss the discovery yesterday of a toxic wastesite, an abandoned hazardous wastesite near a school, near a residential area, near a city gymnasium, and two churches.

It is the same story, different names, different places. I think it is doubtful that these hearings we begin today will resolve the questions that surround the uncertainties medical experts and scientists have about the acute and chronic toxicity to human populations. Nor do I believe this hearing will answer all of the questions that arise in attempting to resolve the issue of whether there is a need for change in Federal law to provide for victims of hazardous waste and other pollution.

Such certainty may never exist, but the absence of total certainty does not necessarily mean we must do nothing but wait for a body count before we act. Indeed we look to learn from what we will hear today and in the days ahead and hopefully we will take the steps necessary to ensure that we as a Nation are providing for the protection of the health and well being of the American people in every way that we reasonably can.

I think these hearings today are particularly important because we are going to be hearing from real life human beings who have experienced the impact of hazardous waste. The fact is that too often the general public and, indeed, even the Congress only find out about what it means where a problem of this sort exists through the cold gray print of a newspaper or a 30-second film clip on television. But we are not talking about plastic people. We are talking about human beings and the effect that this problem has had on their lives.

I think it is exceptionally important and especially needful that we in the Congress hear directly from the people who have been victimized by this problem. Not the people who created it, not the people who condoned it, but the people who have been victimized by it, so that we can get a better insight of just what the dimension of this problem is. We are nowhere near seeing the end of the problem, we are really seeing only the tip of the iceberg.

I think we have an unusual responsibility to find out what it is that needs to be done, what the consequences are if we do nothing. That is what we will be looking for today and that is the reason that as chairman of the subcommittee I express my profound appreciation to the individuals who will be sharing with us their story of misfortune.

Before we proceed I would like to inquire whether my colleague, Mr. Molinari, has an opening statement.

Mr. **Molinari**. Thank you, Mr. Chairman.

I do have a prepared statement, but I think a lot of what I was going to say has been covered by you in your own opening statement.

We have had an awful lot of hearings concerning toxic contamination. I suspect, as we proceed this week to hear from those who have been exposed, that indeed we are going to witness firsthand the kind of problems that are encountered throughout this country. I know I have a constituent here today who will be testifying about the problems she and her family and neighbors have had. It is a sad, tragic story.

When we talk about victims compensation, I ask myself the question, if in fact when Congress enacted the Superfund law, if it had provided for victim compensation, if chemical manufacturers were held responsible with open-ended liability for what would result from the chemicals that they manufacture and sell, would the distribution process be what it is today? If the people that distribute them, and those that have licenses to take the toxic chemicals and bring them to legal dumps were held accountable and legally responsible for the health consequences and property damages sustained by the residents of the communities, would they be as lax as they have been in the past?

I suspect not. And I believe when we conclude these hearings we will be in a better position to help determine the steps that we as Members of Congress should take.

I think, Mr. Chairman, with that, we should proceed to our hearing panel. I think this is the time to hear from them rather than myself.

Thank you very much.

[The statement of Mr. Molinari follows:]

Opening Statement of Hon. Guy V. Molinari

Thank you, Mr. Chairman. I join you in welcoming the witnesses who will be testifying before the subcommittee today, particularly Mrs. Rita Jones, a constituent of mine, about whom I will have more to say later when she is called to the witness table.

Mr. Chairman, the so-called issue of "victim compensation"—seeing that persons who experience health or economic injury from their exposure to toxic chemical wastes are adquately and justly paid for the damages they suffer—is a problem of many dimensions viewed in many different ways, depending upon whom you talk with.

In this subcommittee's series of oversight hearings on the Superfund law, we have repeatedly heard from local and State health authorities and EPA officials about the criteria they employ in deciding whether or not to order the closure or cleanup of a particular landfill or waste disposal site. This "risk assessment" process, although often guided by statutory or regulatory thresholds such as "substantial threat to human health and safety," we have found, I believe, to be extremely loose and judgmental in application. The result: Hundreds, if not thousands, of toxic waste disposal sites across the country continue to pose health threats to nearby residents.

Perhaps the real experts we should be listening to are those who are exposed daily to the human health threats associated with drinking water and breathing air contaminated by toxics emanating from waste dump sites. I personally know of such people: Rita Jones is one; other residents of my congressional district are forced to live under the same conditions; the landfill workers for the city of New York, who have recently approached me about their health problems, are others.

What better evidence of threats to human health can be gathered than to talk with and observe persons who suffer chronic respiratory difficulties, higher than normal rates of cancers and birth defects, bladder and kidney disorders, and other medical problems? These are the real experts! They don't need to be told about "threats to human health;" they live with these discomforts and tragedies on a daily basis, while wondering what it takes to convince unresponsive local, State, and Federal Government authorities that there is a problem which needs to be corrected.

I am not unmindful of the medical, scientific, and legal uncertainties involved in this entire issue. The truth of the matter is that there are people out there who are suffering from illnesses of mysterious or unknown origins, who are experiencing real economic hardship and real fears that their current health problems may be but precursors to greater difficulties some time in the future. To them, I suspect, the administration of the Superfund law hasn't been so "super" after all.

One key point which I think the members should keep in mind as we go through this series of hearings: We should remind ourselves of the root cause—toxic chemical contamination—of the victim compensation issue we're addressing. While we do so, consider these alternatives: (1) If we do nothing on victim compensation, leave the legal system alone such that deserving persons face an almost impossible task in recovering monetary damages from toxic chemical generators, have we done anything to encourage chemical manufacturers to clean up their operations by reducing or eliminating their wastes? or, (2) if Congress does enact a victim compensation statute, under which manufacturers could face enormous potential liabilities, have we provided the very type of financial incentive needed to eliminate the root causes of the victim compensation problem?

Our job, aided by the testimony we will hear during these hearings, is to identify the appropriate means by which we can justly and adequately address the victim compensation problem. To that end, I look forward to some extremely productive sessions.

Thank you, Mr. Chairman.

Mr. Levitas. Thank you for your comments.

Dr. Rowland.

Mr. Rowland. No opening statement, Mr. Chairman.

Mr. Levitas. Thank you.

Before proceeding I want to mention two other things. First, as you know, the subcommittee has been continuing its investigation of EPA's handling of two site cleanup efforts, one of which to the

Seymour Recycling site in Seymour, IN, and various actions by EPA officials pertaining to the settlement on that case last fall. I now believe that we will be able to schedule hearings on that part of our inquiry either during or shortly after the August recess. We will make an announcement about that hopefully next week.

Also, with respect to the matter of how the Department of Defense is handling its hazardous waste disposal problems, I believe we may be able to schedule a day of hearings on that either prior to the August break or during the August recess. Hopefully next week we will be able to announce a specific hearing time. There will be one or two other matters added to our agenda as well with respect to some followup on matters that were raised during the first phase of our hearings.

One announcement I want to make to all of the witnesses today. This committee is an investigation and oversight committee. Accordingly, all testimony taken before this subcommittee is taken under oath. I don't want you to think there is any special procedure today in that regard.

And so in the interest of time, if all of the witnesses here today who are scheduled to testify will at this point raise your right hands, I will administer the oath to all of the witnesses at one time.

[Witnesses sworn.]

Mr. LEVITAS. Thank you very much.

We are very pleased to have with us today to introduce the first witness not only a colleague of ours, but a distinguished member of this committee, a subcommittee chairman of this committee, and someone who has been extremely active and interested in this problem for quite some time. Indeed, Congressman Young has on frequent occasions called to this subcommittee's attention specific matters and asked for our assistance and cooperation with particular matters relating to the situation in Missouri as well as the entire problem.

And so it is with that background and with appreciation that I recognize our colleague, Congressman Bob Young, for purposes of introducing the first witness. And upon conclusion of that, I will invite Congressman Young to join us on the panel if he so desires.

Mr. Young.

Mr. YOUNG. Thank you, Mr. Chairman.

I want to take this opportunity to thank you and the other members of the subcommittee for giving me the opportunity to appear here this morning as these very important hearings open. I want to commend you, Mr. Chairman, and the ranking minority member, Mr. Molinari, and the members for your continued oversight and determined work in an area of what has become our Nation's most pressing and immediate environmental concern, the proper management and cleanup of hazardous waste materials.

I appear before you today to introduce a woman, and a public servant, who perhaps better than anyone in the Nation, can provide these hearings with a firsthand impression of the hardship, loss, turmoil and tragedy that toxic waste contamination can bring to a community, and to individual lives. She is Marilyn Leistner, mayor of Times Beach, MO, the small town in my congressional district that has become a modern day ghost town due to the presence of high levels of dioxin and the unusually severe flooding along the Meramec River last December.

Because of the severity and suddenness of the dangerous situation in Times Beach, it has served as a kind of testing ground for EPA responsibility and action under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, also known as Superfund.

Mr. Chairman, after dioxin was discovered throughout the town of Times Beach and the town was virtually destroyed by floods, it was clear to me that some action had to be taken to eliminate the so-called double whammy effect that plagued this community. It had become apparent to me by January 4 of this year that a complete buyout of the town constituted the only way to treat the citizens of Times Beach fairly. The majority of homes and businesses had been demolished from the floods and it made little sense to let these people come back into town and try to rebuild their lives with the threat of dioxin contamination everywhere. In fact, the Center for Disease Control had issued health warnings for the residents not to return to Times Beach for this very reason.

Only after wrestling with redtape, and coordinating all the levels of Government with responsibility for toxic wastes and disaster assistance we were able to bring into effect the offer of the Federal Government to buy out the town and relocate the residents from harm's way. The contracts for the buyout were signed by all parties last month, and the process of appraising the property of Times Beach residents is going on today. Without a doubt, this buyout is absolutely essential as compensation to the innocent victims of the Times Beach disaster, anything less would have been an injustice to the citizens of that troubled community.

Mayor Leistner has seen her friends, her relatives and the people she represents, forced to abandon their homes and businesses. She has worked tirelessly with my staff, EPA, FEMA, the State and local governments in trying to settle on what is proper compensation for the uprooting of these people's lives. Hers has been the monumental task of holding together a community that dioxin has done so much to tear apart. For these reasons, I am sure the subcommittee will benefit greatly from her testimony.

Mr. Chairman, in conclusion, I would respectfully urge the committee to consider how the former residents and businesses are coping in their attempts to rebuild their lives, assess the true economic loss of businesses in Times Beach and whether there is a Federal role in compensation for those businesses, and finally, evaluate the prospects that the victims will ever be fully compensated for their injuries through legal actions against those parties who generate, dispose of, or operate disposal facilities for toxic chemical wastes.

These are only a few of the many issues which your committee must investigate, and I pledge to you I will do all that I can to assist you in your efforts. Mr. Chairman, it is my understanding that the mayor has Mr. Laine Jumper and Mr. Charles Stone here to assist in any questions the committee may have. Mr. Jumper was appointed by the President on the Dioxin Task Force and Mr. Stone is a private businessman.

I want to thank you very much for your attention to this matter. I am sure this subcommittee with its history of trying to get to the bottom of problems will do everything it can to rectify these very bad situations.

Thank you very much, Mr. Chairman. I appreciate the opportunity to come up with the committee.

Mr. LEVITAS. We are pleased to have you with us.

Mr. YOUNG. Mr. Chairman, I don't know, I asked Mr. Jumper and them to put up their hand to be sworn in. Would you want them at the front table with the mayor?

Mr. LEVITAS. I think it would be a good idea.

Madam Mayor, and others from Times Beach, we are pleased to have you with us.

TESTIMONY OF MARILYN LEISTNER, MAYOR, CITY OF TIMES BEACH, MO, ACCOMPANIED BY CHARLES STONE, MELBA PERSCHBACHER, AND LAINE JUMPER

Mrs. LEISTNER. Thank you, Mr. Chairman.

At this time, I would like to take the opportunity to thank Congressman Young for his very dedicated efforts on behalf of the people of Times Beach.

Thank you very much, Congressman Young.

Mr. Chairman, members of the committee and staff, I first want to thank you for the invitation to speak to you about the trials and trauma of Times Beach, MO.

The personal interest that you and our Congress are showing prompts me to speak from my heart.

My name is Marilyn Leistner, mayor of Times Beach, MO, formerly alderwoman, chairman of the board, and acting mayor. I have lived in Times Beach since 1956 and have raised 4 children there. Times Beach is about 1 square mile in size and housed 800 families, about 2,200 people.

It was first subdivided before 1910 into 20 by 100 lots which were given away by the St. Louis Star-Times Newspaper in an advertising program. One free lot with a 3-year subscription to the newspaper. Being located directly on the Meramec River, with its sandy bank, it became known as Times Beach and began being used as a weekend resort and fishing area.

When the depression hit, some people moved into their weekend cottages permanently to ride out the hard times. The town grew slowly and in 1956 it voted to become a village and in 1957 it incorporated as a fourth-class city in order to maintain home rule. Improvement and growth were slow but steady until the recession of the early seventies. Construction of two mobile home parks nearly doubled the population and tight money and credit made the relatively inexpensive land in the Beach quite attractive to young do-it-yourselfers to buy a house or lot and build or fix up themselves. This transformation continued until the late seventies when many new homes were built and many old ones totally rehabbed.

When the dioxin flood disasters hit in December 1982, Times Beach was nearing completion of a metamorphosis from a rundown poor river town to a lower middle class community. Massive cleanup campaigns of abandoned buildings and junk were ongoing and showing success. Progress in the face of economic recession was a source of pride for nearly everyone.

As mayor of Times Beach, I have seen our community transformed from a growing working small class town on a scenic Ozark river to a national symbol of something unclean and uninhabitable. I have heard the talk about Times Beach change from gossip at the park benefit barbecues to nightly jokes by Johnny Carson on the "Tonight Show."

At this time I would like to show you the type of jokes I am referring to. This is the River Front Times weekly newspaper, St. Louis. On the front it says, "Eternal Bliss: Missouri's Most Famous Waste Hauling Family Keeps on Trucking. What do Charles Kuralt, Willie Nelson, and the Grateful Dead all have in common? They are all on the road again."

These are the types of jokes our community has been subjected to since the announcement in November of the dioxin on the streets.

I have felt the pride of accomplishment of a young couple, who had just completed the building of their own home with their own hands, melt into despair and fear as their hard-won dream disappeared into a contaminated ruin. I have shared the joy of an elderly woman who found some small treasure thought lost in the mud and debris and have cried along with a 23-year-old girl terrified of having children for fear her babies will be born deformed. I have seen the very best come out in some people and the very worst in others.

The one true constant seen in all the people, however, is the simple fact that everyone's life has been brutally and irrevocably changed. Gone forever are the friends and neighbors of 5, 20, and 30 years standing. Gone forever are those people who were your babysitters and lawn cutters, your pinochle partners and bowling buddies, your schoolmates and favorite teachers.

When I ran for this office 2½ years ago, if I had known I would wind up in Washington, I would have probably hidden in my closet. You will have to forgive me if I appear a little nervous. I am not really a public person.

Gone is the guy down the street who would trade a tuneup on your truck for a paint job on his porch. Gone is the lady you used to go "garage saling" with. Gone is the local watering hole where you stopped on Wednesday night to have a beer with the people you knew and enjoyed. Gone is the church where you first prayed or said "I do" or simply worshipped on Sunday.

Gone is the cop you called Mike who watched your house while you were down at the lake. Gone are the town meetings where you hollered about potholes in the roads and blamed the aldermen for some things and the mayor for everything. Gone are the smalltown politics, the smalltown problems, and the fierce smalltown pride. Gone is the reverend who read your water meter, and the Indian who graded your yard. Gone forever is everything that made the beach your home, the one place on Earth that gave you the sense of belonging and security and love that you could obtain nowhere else.

The news media has been filled recently with an abundance of shows, articles, specials, and reports about Times Beach and contamination. But the media has yet to communicate what the disasters have actually done to our people, what the reality of our lives truly is, and what the future holds for us.

No one in our immediate area was familiar with dioxin or the possible effects of exposure to this chemical. The fear of the people was all the greater because of their limited knowledge. Children were avoided by their classmates. Mothers from adjoining communities advised their children to avoid contact with Times Beach children. In one instance, an old business associate refused to shake hands with a Times Beach businessman and cited possible dioxin contamination as the reason.

Cleaning establishments refused to accept the clothing of Times Beach residents because of possible contamination and in one very bizarre happening, one man entered a McDonald hamburger restaurant, was recognized from being on television, pointed at, someone said, "He's from Times Beach," and the entire McDonald's Restaurant emptied. Even simple things like trading an automobile was made difficult because the dealers were afraid of dust contamination on the used car since it had been in Times Beach. In innumerable ways, the flood, coupled with the dioxin disaster, has caused untold misery to the people of Times Beach.

Much has been made and said about the Federal buyout of Times Beach. I want to take this opportunity to thank the Federal Government for the aid and comfort extended to us under the various disaster relief programs. I am proud and grateful to live in a country where such aid is a matter of law and course. The immediate Federal flood relief was swift and comprehensive. Emergency shelters were made available and the Red Cross and Salvation Army did a magnificent job in responding to our need for food, clothing, and temporary shelter.

This brings up a most important point about the whole Times Beach situation. If our only problem had been the floods, we would have been 95 percent recovered by now, the end of July. Massive efforts were underway, even before the waters receded to collect debris and organize work teams to help restore our homes. Assistance and volunteers in the best of American tradition came pouring in from surrounding areas.

All these efforts, donations, and work, however, came to an abrupt and incredible halt on December 23 when barricades were placed on roads leading into the town, and the Center for Disease Control in Atlanta issued a strong warning to the effect that if you were in Times Beach, get out; if you were out of Times Beach, stay out.

The State of Missouri subsequently declared the entire town an imminent health hazard. For people who owned or rented homes in Times Beach there were small Federal and State grants for the repurchasing of furniture and other personal items if qualifications were met. Many could not meet the qualifications. Federal and State authorities also made some provisions for temporary housing, in apartments, mobile homes, motels, wherever emergency temporary housing was available.

City employees lost not only their homes, but their livelihood and thus experienced a double hardship. I was not mayor at the time the problems exploded, but was a member of the board of aldermen. The pressures on the Times Beach mayor were so great that two successive mayors resigned for personal reasons.

Hopes for a new Times Beach soared when the Army Corps of Engineers proposed rebuilding the city on unused Federal park ground directly adjacent to the city of Times Beach. This was also the recommendation of the Federal emergency flood hazard mitigation report prepared in response to President Reagan's disaster declaration of December 10, 1982. This proposal is one of the specific alternatives defined in the Superfund law. When defining "remedy" or "remedial action," the term includes the costs of permanent relocation of residents and businesses and community facilities where it is determined that relocation is more cost effective than cleanup.

This was the answer to virtually all of our problems but we quickly learned that this was not to be. Under this program, the present problems of the business people would not have developed.

A plan to purchase only the privately owned real estate was announced by EPA Administrator Anne Burford on February 22, 1983. We, city officials and concerned citizens, began an intensive letter writing and lobbying campaign to convince our State legislature to appropriate the necessary matching funds; which indeed occurred. Terms of the State appropriation bill prevented the State from holding title to the ground; so the city of Times Beach was made a party to the Superfund contract to act as interim titleholder.

Throughout this process, numerous questions were put to FEMA asking about various facets of the buyout; concern was intense as to whether or not people would be able to relocate, whether ruined businesses would be compensated to ever reopen elsewhere.

On March 19, 1983, FEMA called a meeting with the residents, and announced the general terms of the buyout. In question and answer form, FEMA made statements such as: "Businesses are generally eligible for similar acquisition and relocation benefits," and "The intent of the program is to make each resident 'whole' again, as they were on November 30, 1982." We, the city officials, were convinced that our people would receive compensation sufficient for them to start over somewhere else. That the businesses would be made "whole" again as "free of defect or impairment, intact. Whole implies that nothing has been omitted, ignored, abated, or taken away." We were told by FEMA that the purpose of the buyout was to make everyone whole again as they were before the flood and announcement of the contamination.

We are not whole unless the economic injury we have suffered is recognized and compensation to cover that injury is provided.

According to the terms of the relocation brochure distributed businesses are eligible to receive up to a maximum $10,000 relocation expense payment. You are disqualified from even that, if you have a similar business elsewhere. This $10,000 sounds like a lot until you analyze the circumstances of some businesses in Times Beach. I will hit the highlights of some particular instances. Detailed sheets for each are attached.

The owner of a gas station/liquor store known as Jim's Fina—Jim and Leon's Corp.—has invested $50,000 in inventory and purchase of the business. Not owning the real estate, he will receive at best the $10,000, but probably only the minimum $2,500 because he has no inventory left to move. He not only lost his $20,000 year income, but all of his business investment. Ineligible for SBA disaster loans, he has nothing to look forward to except many years of paying off his business loan and probable bankruptcy.

Steve and Marianne Hrin moved their family owned auto body shop business to Times Beach in 1979. Times Beach's prime location on a major interstate seemed ideal. The flood cost them only 3 weeks. The dioxin cost them their business of 29 years. The $10,000 won't even move one frame alignment rack, much less 40 tons of other equipment. The purchase of their real estate will not even begin to compensate them for the loss of a thriving business. Laying off their employees, has resulted in a huge jump in their unemployment taxes and insurance costs. Mrs. Hrin wrote, "We were a classic example of the American dream come true; work hard, invest wisely and save regularly." The failure of the Superfund law to provide business-oriented compensation again has shattered forever another American dream.

The largest business in Times Beach, the two mobile home parks, is owned by Mr. Charles Stone. Included in his business was a used home brokerage firm and a laundromat. With all 337 mobile home pads empty of paying customers, he has to borrow to pay his $17,000 per month interest payments. Active in the buyout negotiations, he repeatedly was assured by FEMA that he would be "made whole again" by midsummer.

The reality of his buyout is that he will be forced deeply into debt to finance the tripled cost of a new park. The 8-month delay in solving the dilemma of Times Beach is causing the accumulated interest to eat up a substantial part of his buyout proceeds and working capital. Without compensation, Mr. Stone will lose most of his equity and will basically be starting a $4 million business in a very uncertain economic climate and in a much less desirable location.

J.C. and Doris Walters, owners of KOA Kampground, face virtually unsurmountable relocation odds. They have lost the 1983 season and will lose the 1984 season because it is already too late to advertise in the 1984 nationwide directories that bring them 80 percent of their business. Their new campground is not yet under construction as they are awaiting the buyout funds which will enable them to start construction of their new campground. Being the closest to St. Louis and near the Six Flags Amusement Park on I-44 was a prime location. This campground was located approximately 2 miles from Six Flags Over MidAmerica.

There is simply no good ground available with the perfect highway access that KOA had. The Walters are ineligible for the $10,000 relocation allowance because they own a small campground elsewhere.

I could go on about Robert Fitts, who had nine rental mobile homes. These have turned into nine overdue payments each month. Or, Melba Perschbacher, who has two commercial properties with 10-year leases. She no longer has her assured retirement income but she still has the burdensome debt of her mortgage payments.

I could describe 30 more owner-operated concerns who face the loss of everything without help. How many of these will ever be able to reopen? How much unemployment will result? Additional hardship cases are attached.

However large the financial toll has proven to be, the human toll remains. The fact is that we have been the rope in this tug of war. So much controversy has surrounded dioxin, as one doctor has said, that dioxin is the most studied chemical today and still no serious harmful effects are known. However, the Missouri Department of Natural Resources in a letter to Alden Shields, dated August 17, 1982, states "Dioxin acts as a toxin, carcinogen, mutagen, and fetal toxin * * *".

At this time I would like to quote a manual I have used very much since the day it was sent to me. On page 223 of the EPA Manual, it says several deaths related to the TCDD have been recorded. Some due to liver damage and others to chronic exposure to the chemical.

Additionally symptoms such as chloracne can be passed by an exposed person to close associates, such as family members through holding hands or other close contact.

The concern of serious health effects is a real one for the people of Times Beach, but it is more in the nature of a long range concern for most of us. Others are not so fortunate.

At an intersection of "hot streets" lived four families. Mr. and Mrs. Lewis Bierman moved to Times Beach in 1975. In February 1978, Linda suffered a miscarriage. In March 1979 she gave birth to Melissa, who had congenital neuroblastoma, a rare cancer in infants. Melissa died 4 months later. After having been assured by doctors that having another child was a one in a 300,000 chance, Linda bore Jessica in December 1980.

Tragically, Jessica, too, has neuroblastoma cancer and undergoes chemotherapy and radiation treatments every 5 weeks. Her prognosis is very poor. Their tremendous financial burden is made much worse by the cutbacks in insurance coverage by Mr. Bierman's employer. By the way, he is a Federal employee and in 1979 his insurance was cut back by 15 percent. Future health insurance may become unobtainable as companies exclude people who have lived in known contaminated areas.

There are other people I have here who have had health problems. They do not want their names to be used because they do not want to be harassed by the media. And in Times Beach, MO, you had all the press, TV stations and media practically living with you since December 5 of last year.

Across the street lived Mr. and Mrs. "A". After living there about 2 years, Mrs. "A" died mysteriously in childbirth from a massive infection that overwhelmed a depressed immune system. Three years later the baby died with a similar disorder.

Next door to Mr. "A" lived Mr. and Mrs. Laine Jumper. A baby born in 1971 died 10 months later from a heart defect. Mr. Jumper suffered an acute neuroestenia in 1978 resulting in 8 weeks hospitalization and 6 months lost work. Consulted neurologists couldn't explain the depressed nerve functions and personality problems but did say that it could be environmentally related. Somewhat recovered, Mr. Jumper has never returned to the physical condition necessary to his business and medical insurance is unaffordably expensive.

Mr. Chairman, at this time I would like to tell a story. I have not been a public person about the health of my children, but since 1977 three of my four children have developed severe health problems. I have a 19-year-old daughter who in 1977 developed a very serious seizure disorder. In March of this year she attempted suicide because of the fact that she felt with all the publicity, she had no future, and she felt that the dioxin was very harmful and that she wasn't going to be able to have children or lead a normal life.

You will have to forgive me for getting emotional. I am sorry.

Another daughter, Tammy, 23 years old, has been treated by a doctor for over a year. Three years ago we almost lost her with a hyperthyroid disorder. She also has a hypoglycemia disorder. But she has been treated for the last year for what the doctors are terming precancerous stages of the cervix.

My 24-year-old daughter has a very serious disorder, some type of allergy, possibly environmentally related. Her nose, her lips, her eyes swell shut. Her lip swells with her nose. She has been seeing a dermatologist once and twice a month for almost 2 years.

The Bodimer family moved to Times Beach in early 1972. In 1972 their street was heavily sprayed with the contaminated oil. The father started to have heart attacks and problems with diabetes in 1979. By the way, this man, since the December 5 flood is a complete invalid. He even refuses to get out of bed. He feels there is no reason for him to live any more. Both the twin boys in the family after going through the screen held by the Missouri Division of Health Center for Disease Control in Kirkwood, MO, were advised to see a dermatologist. Both teenage boys have now been diagnosed as having chloracne.

The mother, Shirley, has been seeing a dermatologist for the past 3 years. She has a recurring skin rash which cannot be diagnosed as to what is causing it or what it is.

Across town is another neighborhood where seizure disorders are the rule rather than the exception. In a grouping of 15 homes, there are seven families with one or more members suffering a seizure disorder. Directly across the street a small girl 5 years has a serious nose bleed. She wakes up in the morning and her pillow is just covered with blood. This small child also has a seizure disorder. A year ago the mother developed a seizure disorder. They are both on dilantin and phenobarbitol. Behind them a family lived. They had a baby, 18 months old died December 17 from a hydroencephalis, which is water on the brain. These represent only those who were willing to talk in this area.

Two doors down the street from me on the right, a year and a half ago a baby was born with the kidneys on the outside of the body. Perhaps there are others who exist but we have talked about health problems with a lot of people who are unwilling even to discuss their problems.

Telephone repair men assigned to Times Beach 10 years developed severe rashes on their hands and feet that subsided only after transferring to other areas. One of these telephone men I had the opportunity to carry on a conversation with in the Kroger store at Eureka, MO. The rash is very bad on his arms. He hasn't been able to find anything to treat the rash. I referred him to St. Joseph's Hospital for the health screening.

There have been numerous young women with breast cancer; some in their teens. A city employee had a daughter develop seizures after moving into Times Beach. One incredible irony involves a former mayor who received a medical retirement after 14 years in the Marine Corps. He had been sprayed in Vietnam with agent orange and developed chronic bone marrow disease, resultant hemophilis, and severe chest pains. His discharge lists an unknown toxin agent as the cause—Dioxin in the agent orange?—how sad to note that he moved to dioxin contaminated Times Beach where his daughter developed severely swollen salivary glands and 2 weeks ago had surgery.

While the human temptation exists to blame anything and everything on dioxin, I have related only problems that have defied diagnosis as to their cause from all facets of the medical community. I have ignored many other normal type problems existing in these people. I truly believe that many severe health problems in Times Beach will be linked to the dioxin; yet, there is no program of compensation for health benefits or insurance or liability clauses for same in the Superfund law as it stands today. There are no provisions for people oriented compensation from environmental diseases. The Superfund law requires polluters to reimburse the fund for cleanup costs, but not for the human costs. Polluters should stand liable under this law for damages to people without the delaying and evasive and costly necessity of civil lawsuits.

There is no compensation for the anguish, stress, and resultant mental health problems suffered by our people. At least four fatal stress related heart attacks have occurred since January. Are they victims of bad hearts or pressure from all of this? At least six complete nervous breakdowns and innumerable near collapses were definitely caused by the problems.

Other uncompensated costs involved the transportation of children to school; an additional 10, 15, and in some instances 80 miles daily while living in temporary housing awaiting the buyout money. We went to the Rockwood School District and asked that the children be allowed to stay in the school district. They had already lost their homes, their community. We felt it would be very tragic for them to be moved from the school district where they had been going to another school district. In September of this year they will have to start in schools in the areas where they are now living.

Most families will be unable to permanently relocate in time to get their children registered for school. If they do get them registered they may have to move again possibly in October, November, or December. There is a shortage of affordable housing in the area, thus forcing many to move farther from work, which raises transportation costs.

What of the future? When the floods came I heard many who had lost everything say, "Well, at least we still have our health." Now, who is to know what our health will be? Lifetime followup of people exposed to dangerous chemicals should be mandatory in order that the toxic timebombs of cancer and pollutant induced disease will be attributed to the proper cause. A fund should be set aside from the Superfund tax on chemicals to provide necessary health care for affected persons. Fund subsidized life and health insurance is another alternative.

There is no provision for compensation for personal property. I appeared on cable news network with Dr. Carnou. His advice to the people of Times Beach was, move out if you are still living there. If you are planning on moving back, don't go back, and don't take absolutely anything with you.

Many people at that time destroyed everything that they tried to wash or clean up from their homes, thus leaving them with no bedsheets, no clothing, nothing. When the CDC issued it's health warning on December 23, 1982, it advised us to cease all nonemergency cleanup and leave everything undisturbed because of the possibility of contamination. Most of us heeded that warning and did not attempt cleanup of clothes, furniture, tools, and other personal property from the flood. A lot of people never returned to their homes from the December 5 flood.

It wasn't until February 23, 1983, that the EPA concluded that we could go ahead and remove our things, with proper cleaning. What vandals and thieves didn't destroy, 2½ months of rotting in mud and debris did. The buyout will not compensate anyone for any losses of this nature. Small Federal grants to us of $5,000 only go a small way to replace a lifetime's accumulation and most did not even qualify for the grant. Businesses were told that SBA loans were available. Almost all applied and almost all were refused. There was no ready money for the business people and they have suffered accordingly.

Trying to summarize the agonizing death of our city is difficult. This experience has been an emotional roller coaster ride for 2,000 people. Peaks of hope one day to be followed by a plunge into despair the next.

We suffered the worst flood in our recorded history on December 5, 1982. Were that the only problem we would have prevailed without Federal aid, but this monster called dioxin has removed any clear cut goals from our lives and left nothing but questions, doubt, and an underlying knowledge that things will never be the same again. Should there ever be another Times Beach in another location, at some future date we would suggest the following:

For business people:

First, adequate replacement value and relocation.

Second, where a business cannot be relocated fairly then just compensation for the value of the business enterprise.

Third, no resident or business can relocate without knowing: The amount of money available for rebuilding; and a definite date the money will be available.

Fourth, equal grants for business people who have lost income as for residents who have lost shelter.

Fifth, consideration for the ongoing expenses of the business community, such as mortgages, insurance, inventory, debt, et cetera.

Sixth, speed. The need to make the above needed information available as rapidly as possible cannot be overemphasized.

For the entire community:

First, compensation for personal property declared contaminated.

Second, compensation from polluters for health problems with strict liability clauses.

Third, lifetime followup of exposed persons.

Fourth, detailed Federal guidelines to provide consistent, equitable treatment for residences, businesses, and local government.

Fifth, mandatory uniform State Superfund laws to guarantee State government cooperation as well as necessary matching funds.

Sixth, implementation of extraordinary remedies where such measures are warranted as opposed to taking the cheapest way out.

These are our recommendations to you. It has come to our attention that Senators Danforth and Eagleton have sponsored legislation which will correct some of these inequities. However, it appears this legislation will not be passed in time for it to help the people of Times Beach. Our people need to come under the provisions you are making for others. We ask that you please amend your bill to include us.

The laws need to be changed. Provisions for extraordinary response, such as relocating entire communities as described in section 101, PPH 24, should be implemented where it is warranted, uniform mandatory State Superfund laws should be required nationwide, to guarantee necessary State matching funds and a swift response from State officials.

Victim compensation must be included for residents and businesses that suffer financial and health losses through no fault of their own. Federal response time must be shortened. Some of these cannot be applied to us; in other areas by amending the Superfund law and making it retroactive to include Times Beach, some of our serious problems can be alleviated.

I have presented here the unexaggerated truth. I feel that the intent of Congress in passing the Superfund law was not in the areas of response to and compensation in the Federal effort at Times Beach. I ask that you, the committee, consider these facts and make appropriate recommendations to the full Congress. I thank you sincerely for myself and the people of Times Beach for your interest. In calling home last night I have learned that in the State of Missouri there are now 165 potential sites, 31 confirmed at this time. The possibility does exist now that anyone who permanently relocates from Times Beach may possibly move to another contaminated site.

Thank you very much and God bless you all.

[Attachments to the Leistner statement follow:]

STATEMENT OF MARILYN LEISTNER, MAYOR OF TIMES BEACH, MO

Mr. Chairman, Members of the Committee, and Staff: I, first, want to thank you for the invitation to speak to you about the trials and trauma of Times Beach, Missouri.

The personal interest that you, our Congress, are showing prompts me to speak from my heart. My name is Marilyn Leistner, Mayor of Times Beach, Missouri; formerly Alderwoman, Chairman of the Board, and Acting Mayor. I have lived in Times Beach since 1956 and have raised four children there. Times Beach is about one square mile in size and housed 800 families, about 2,200 people. It was first subdivided before 1910 in 20′ x 100′ lots which were given away by the St. Louis Star-Times Newspaper in an advertising program. One free lot with a three year subscription to the newspaper. Being located directly on the Meramec River, with its sandy bank, it became known as Times Beach and began being used as a weekend resort and fishing area. When the depression hit some people moved into their "weekend" cottages permanently to ride out the hard times. The town grew slowly and in 1956 it voted to become a "village" and in 1957 it incorporated as a fourth class city in order to maintain "home rule." Improvement and growth were slow but steady until the recession of the early seventies. Construction of two mobile home parks nearly doubled the population and tight money and credit made the relatively inexpensive land in the Beach quite attractive to young "do-it-yourselfers" to buy a house or lot and build or "fix-up" themselves. This transformation continued until the late seventies when many new homes were built and many old ones totally "rehabbed". When the dioxin-flood disasters hit in December 1982 Times Beach was nearing completion of a metamorphosis from a run-down poor river town to a lower middle class community. Massive clean up campaigns of abandoned buildings and junk were on going and showing success. Progress in the face of economic recession was a source of pride for nearly everyone.

As Mayor of Times Beach, I have seen our community transformed from a growing working class small town on a scenic Ozark river to a national symbol of something unclean and uninhabitable. I have heard the talk about Times Beach change from gossip at the park benefit barbecues to nightly jokes by Johnny Carson on the Tonight Show. I have felt the pride of accomplishment of a young couple, who had just completed the building of their own home with their own hands, melt into despair and fear as their hard won dream disappeared into a contaminated ruin. I have shared the joy of an elderly woman who found some small treasure thought lost the mud and debris and have cried along with a 23 year old girl terrified of having children for fear her babies will be born deformed. I have seen the very best come out in some people and the very worst in others. The one true constant seen in all the people, however, is the simple fact that everyone's life has been brutally and irrevocably changed. Gone forever are the friends and neighbors of 5, 20, and 30 years standing. Gone forever are those people who were your babysitters and lawncutters, your pinochle partners and bowling buddies, your schoolmates and favorite teachers. Gone is the guy down the street who would trade a tune-up on your truck for a paint job on his porch. Gone is the lady you used to go "garage sale-ing" with. Gone is the local watering hole where you stopped on Wednesday night to have a beer with the people you knew and enjoyed. Gone is the church where you first prayed or said "I do" or simply worshiped on Sunday. Gone is the cop you called "Mike" who watched your house while you were down at the lake. Gone are the town meetings where you hollered about potholes in the roads and blamed the aldermen for some things and the mayor for everything. Gone are the small town politics, the small town problems and the fierce small town pride. Gone is the Reverend who read your water meter, and the Indian who graded your yard. Gone forever is everything that made "The Beach" your home—the one place on earth that gave you the sense of belonging and security and love that you could obtain nowhere else.

The news media has been filled recently with an abundance of shows, articles, specials and reports about Times Beach and contamination. But the media has yet to communicate what the disasters have actually done to our people, what the reality of our lives truly is and what the future holds for us.

No one in our immediate area was familiar with dioxin or the possible effects of exposure to this chemical. The fear of the people was all the greater because of their limited knowledge. Children were avoided by their classmates. Mothers from adjoining communities advised their children to avoid contact with Times Beach children. In one instance an old business associate refused to shake hands with a Times Beach businessman and cited possible dioxin contamination as the reason. Cleaning establishments refused to accept the clothing of Times Beach residents because of possible contamination and in one very bizarre happening one man entered a McDonald hamburger restaurant, was recognized from being on television, pointed at; someone said "He's from Times Beach" and the entire McDonald's Restaurant emptied. Even simple things like trading an automobile was made difficult because the dealers were afraid of dust contamination on the used car since it had been in Times Beach. In innumerable ways the flood, coupled with the dioxin disaster, has caused untold misery to the people of Times Beach.

Much has been made and said about the Federal buyout of Times Beach. I want to take this opportunity to thank the Federal Government for the aid and comfort extended to us under the various disaster relief programs. I am proud and grateful to live in a country where such aid is a matter of law and course. The immediate Federal flood relief was swift and comprehensive. Emergency shelters were made available and the Red Cross and Salvation Army did a magnificent job in responding to our need for food, clothing, and temporary shelter. This brings up a most important point about the whole Times Beach situation. If our only problem had been the floods we would have been 95% recovered by now, the end of July. Massive efforts were under way, even before the waters receded to collect debris and organize work teams to help restore our homes. Assistance and volunteers in the best of American tradition came pouring in from surrounding areas. All these efforts, donations, and work, however, came to an abrupt and incredible halt on December 23rd when barricades were place on roads leading into the town, and the Center for Disease Control, Atlanta issued a strong warning to the effect that if you were in Times Beach—get out; if you were out of Times Beach—stay out. The State of Missouri subsequently declared the entire town an "imminent health hazard". For people who owned or rented homes in Times Beach there were small Federal and State grants for the repurchasing of furniture and other personal items if qualifications were met. Many could not meet the qualifications. Federal and State authorities also made some provisions for temporary housing, in apartments, mobile homes, motels, wherever emergency temporary housing was available. City employees lost not only their homes, but their livelihood and thus experienced a double-hardship. I was not mayor at the time the problems exploded, but was a member of the Board of Aldermen. The pressures on the Times Beach mayor were so great that two successive mayors resigned for personal reasons.

Hopes for a new Times Beach soared when the Army Corps of Engineers proposed rebuilding the city on unused Federal park ground directly adjacent to the city of Times Beach. This was also the recommendation of the Federal Emergency Flood Hazard Mitigation Report prepared in response to President Reagan's disaster declaration of 10 December '82. This proposal is one of the *Specific Alternatives* defined in the Superfund Law. When defining "Remedy" or "Remedial Action", "the term includes the costs of permanent relocation of residents and businesses and community facilities where it is determined that relocation is more cost effective then clean up." This was the answer to virtually all of our problems but we quickly learned that this was not be. Under this program the present problems of the business people would not have developed.

A plan to purchase only the privately owned real estate was announced by E.P.A. administrator, Anne Burford, on February 22, 1983. We (city officials and concerned citizens) began an intensive letter writing and lobbying campaign to convince our State Legislature to appropriate the necessary matching funds; which indeed occurred. Terms of the State Appropriation Bill prevented the State from holding title to the ground; so the City of Times Beach was made a party to the Superfund Contract to act as interim titleholder. Throughout this process numerous questions were put to F.E.M.A. asking about various facets of the buyout; concern was intense as to whether or not people would be able to relocate, whether ruined businesses would be compensated to ever reopen elsewhere. On March 19, 1983, F.E.M.A. called a meeting with the residents, and announced the general "terms" of the buyout. In question and answer form F.E.M.A. made statements such as: "Businesses are generally eligible for (similar) acquisition and relocation benefits", and "The intent of the program is to make each resident 'whole' again, as they were on November 30, 1982." We, the City Officials, were convinced that our people would receive compensation sufficient for them to start over somewhere else; that the businesses would be made "whole" again and recover. Webster's Dictionary defines "whole" as "free of defect or impairment, intact;" "whole implies that nothing has been omitted, ignored, abated, or taken away". We are not "whole" unless the economic injury we have suffered is recognized and compensation to cover that injury is provided.

According to the terms of the "Relocation Brochure" distributed businesses are eligible to receive up to maximum $10,000 relocation expense payment. You are disqualified from even that, if you have s similar business elsewhere. This $10,000 sounds like a lot until you analyze the circumstances of some businesses in Times Beach. I'll hit the highlights of some particular instances—detailed sheets for each are attached.

The owner of a gas station/liquor store known as Jim's Fina (Jim and Leon's Corporation) had invested $50,000 in inventory and purchase of the business. Not owning the real estate, he will receive at best the $10,000; but probably only the minimum $2,500 because he has no inventory left to move. He not only lost his $20,000 yearly income, but all of his business investment. Ineligible for S.B.A. disaster loans, he has nothing to look forward to except many years of paying off his business loan and probable bankruptcy.

Steve and Marianne Hrin moved their family owned auto-body shop business to Times Beach in 1979. Times Beach's prime location on a major interstate seemed ideal. The flood cost them only three weeks—the dioxin cost them their business of 29 years. The $10,000 won't even move one frame alignment rack, much less 40 tons of other equipment. The purchase of their real estate will not even begin to compensate them for the loss of a thriving business. Laying off their employees, has resulted in a huge jump in their unemployment taxes and insurance costs. Mrs. Hrin wrote, "We were a classic example of the American Dream come true; work hard, invest wisely, and save regularly". The failure of the Superfund law to provide business oriented compensation again has shattered forever another "American Dream".

The largest business in Times Beach, the two mobile home parks, is owned by Mr. Charles Stone. Included in his business was a used home brokerage firm and a laundromat. With all 337 mobile home pads empty of paying customers, he has to borrow to pay his $17,000 per month interest payments. Active in the buyout negotiations, he repeatedly was assured by F.E.M.A. that he would be "made whole again" by midsummer. The reality of his buyout is that he will be forced deeply into debt to finance the tripled cost of a new park. The eight month delay in solving the dilemma of Times Beach is causing the accumulated interest to eat up a sustantial part of his buyout proceeds and working capital. Without compensation, Mr. Stone, will lose most of his equity and will basically be starting a four million dollar business in a very uncertain economic climate and in a much less desirable location.

J.C. and Doris Walters, owners of KOA Kampground face virtually unsurmountable relocation odds. They have lost the 1983 season and will lose the 1984 season because it is already too late to advertise in the 1984 nationwide directories that bring them 80% of their business. Their new kampground is not yet under construction as they are awaiting the buyout funds which will enable them to start construction of their new campground. Being the closest campground to St. Louis and near the Six Flags Amusement Park on I–44 was a prime location. There is simply no good ground available with the perfect highway access that KOA had. The Walters are ineligible for the $10,000 relocation allowance because they own a small campground elsewhere.

I could go on about Robert Fitts, who had nine rental mobile homes. These have turned into nine overdue payments each month. Or, Melba Perschbacher who has two commercial properties with 10 year leases. She no longer has her assured retirement income but she still has the burdensome debt of her mortgage payments.

I could describe thirty more owner-operated concerns who face the loss of everything without help. How many of these will ever be able to reopen? How much unemployment will result? Additional hardship cases are attached.

However large the financial toll has proven to be, the human toll remains. The fact is that we have been the rope in this tug-of-war. So much controversy has surrounded dioxin, as one doctor has said, that dioxin is the most studied chemical today and still no serious harmful effects are known. However, the Missouri Department of Natural Resources in a letter to Alden Shields, dated August 17, 1982 states "Dioxin acts as a toxin, carcinogen, mutagen, and fetal toxin . . . ."

The concern of serious health effects is a real one for the people to Times Beach, but it is more in the nature of a long range concern for most of us. Others are not so fortunate.

At one intersection of "hot streets" lived four families. Mr. and Mrs. Lewis Bierman moved to Times Beach in 1975. In February, 1978, Linda suffered a miscarriage. In March, 1979 she gave birth to Melissa, who had congenital neuroblastoma, a rare cancer in infants. Melissa died four months later. After having been assured by doctors that having another such child was a 1 in 300,000 chance, Linda bore Jessica in December, 1980. Tragically, Jessica, too, has neuroblastoma cancer and undergoes chemotherapy and radiation treatments every five weeks. Her prognosis is very poor. Their tremendous financial burden is made much worse by the cutbacks in insurance coverage by Mr. Bierman's employer. Future health insurance may become unobtainable as companies exclude people who have lived in known contaminated areas.

Across the street lived Mr. and Mrs. "A". After living there about two years, Mrs. "A" died mysteriously in childbirth from a massive infection that overwhelmed a depressed immune system. Three years later the baby died with a similar disorder.

Next door to Mr. "A" lived Mr. and Mrs. Laine Jumper. A baby born in 1971 died ten months later from a heart defect. Mr. Jumper suffered an acute neuroestenia (loss of energy) in 1978 resulting in eight weeks hospitalization and six months lost work. Consulted neurologists couldn't explain the depressed nerve functions and personality problems but did say that it could be environmentally related. Somewhat recovered Mr. Jumper has never returned to the physical condition necessary to his business and medical insurance is unaffordably expensive.

Opposite Mr. "A" was Mr. and Mrs. "L" living relatively healthy lives until the time of the oil spraying. Three of Mrs. "L's" four children developed severe problems. One daughter became sterile and has been diagnosed with a pre-cancerous cervix. Another daughter experienced undiagnosed low energy and painful extremities for years. She developed a seizure disorder in her early teens and has resulting emotional and personality problems. A third daughter has a disfiguring and incurable skin disorder over 70% of her body. Mrs. "L", herself, began suffering severe menstrual problems and underwent a total hysterectomy in 1974. The surgeon described the uterine tumors as "something that I, or my collegues had never seen before and still have no diagnoses." She has arthritic joint pain with no arthritis, ringing ears, and neural pain localized in her arms; all undiagnosable by various doctors. Mr. "L" has had the acne and blackheads around the eyes characteristic of chloracne, elevated cholestrol and triglycerides, lower extremity cramps, hyper-irritability, loss of libido and personality changes.

Mr. and Mrs. "C" living behind Mr. and Mrs. "J" have demonstrated undiagnosed medical problems. Mrs. "C" has a degenerative nerve and disc problem in her spine, migraines, and severe female disorders. Their eight year old daughter has monthly kidney and bladder bleeding, as well as personality problems. Mr. "C" is hyper-irritable and experiences fluctuating emotional disturbances and hypertension.

The Bodimer family moved to Times Beach in early 1972. In 1972 their street was heavily sprayed with the contaminated oil.

The father started to have heart attacks and problems with diabetes in 1975.

The twin boys in the family have both been diagnosed as having chloracne.

The mother, Shirley, has been seeing a dermatologist for the past three years. She has a recurring skin rash which cannot be diagnosed as to what is causing it or what it is.

Across town is another neighborhood where seizure disorders are the rule rather than the exception. In a grouping of fifteen homes, there are seven families with one or more members suffering a seizure disorder. One family has a baby born with its kidneys on the outside of its body. Behind them was a baby with a hydroencephalic brain (water on the brain). These represent only those who were willing to talk in this area. Perhaps, others exist who do not discuss health problems. Telephone repairmen assigned to Times Beach ten years developed severe rashes on their hands and feet that subsided only after transfering to other areas.

There has been numerous young women with breast cancer; some in their teens. A City employee had a daughter develop seizures after moving into Times Beach. One incredible irony involves a former major who received a medical retirement after fourteen years in the Marine Corps. He had been sprayed in Vietnam with Agent Orange and developed chronic bone marrow disease, resultant hemophillia and severe chest pains. His discharge lists "an unknown toxin agent" as the cause (dioxin in the agent Orange?). How sad to note that he moved to dioxin contaminated Times Beach where his daughter developed severely swollen salivary glands requiring surgery.

While the human temptation exists to blame anything and everything on dioxin, I have related only problems that have defied diagnosis as to their cause from all facets of the medical community. I have ignored many other "normal type" problems existing in these people. I truly believe that many severe health problems in Times Beach will be linked to the dioxin; yet, there is no program of compensation for health benefits or insurance or liability clauses for same in the Superfund Law as it stands today. There are no provisions for "people oriented" compensation from environmental disasters. The Superfund Law requires polluters to reimburse the fund for cleanup costs; but not for the human costs. Polluters should stand liable under this law for damages to people without the delaying and evasive and costly necessity of civil lawsuits.

There is no compensation for the anguish, stress, and resultant mental health problems suffered by our people. At least four fatal stress related heart attacks have occurred since January—are they victims of bad hearts or pressure from all this? At least six complete nervous breakdowns and innumerable near collapses were definitely caused by the problems. Other uncompensated costs involve the transportation of children to school; an additional 10, 15 and in some instances 80 miles daily while living in "temporary housing" awaiting the buyout money. Most families will be unable to permanently relocate in time to get their children registered for school. Our kids will be forced into new schools away from friends and familiar surroundings. There is a shortage of affordable housing in the area, thus forcing many to move farther from work, which raises transportation costs.

What of the future? When the floods came I heard many who had lost everything say, "Well, at least we still have our health". Now, who's to know what our health will be? Lifetime follow-up of people exposed to dangerous chemicals should be mandatory in order that the "toxic time bombs" of cancer and pollutant induced disease will be attributed to the proper cause. A fund should be set aside from the Superfund tax on chemicals to provide necessary health care for affected persons. Fund subsidized life and health insurance is another alternative.

There is no provision for compensation for personal property. When the C.D.C. issued its health warning on December 23, 1982 it advised us to cease all non-emergency cleanup and leave everything undisturbed because of possible contamination. Most of us heeded that warning and did not attempt clean up of clothes, furniture, tools, and other personal property from the flood. It wasn't until February 23, 1983 that the E.P.A. concluded that we could go ahead and remove our things, "with proper cleaning". What vandals and thieves didn't destroy, two and one-half months of rotting in mud and debris did. The buyout will not compensate anyone for any losses of this nature. Small Federal grants to us of $5,000 only go a small way to replace a lifetime's accumulation and most did not even qualify for the grant. Businesses were told that S.B.A. loans were available. Almost all applied and almost all were refused. There was no "ready" money for the business people and they have suffered accordingly.

Trying to summarize the agonizing death of our city is difficult. This experience has been an emotional roller coaster ride for 2,000 people. Peaks of hope one day to be followed by a plunge into despair the next.

We suffered the worst flood in our recorded history on December 5, 1982. Were that the only problem we would have prevailed without Federal aid but this monster called "dioxin" has removed any clear cut goals from our lives and left nothing but questions, doubt, and an underlying knowledge that things will never be the same again. Should there ever be another "Times Beach" in another location, at some future date we would suggest the following:

1. For the business people:

a. Adequate "replacement value" and "relocation compensation"

b. Where a business cannot be relocated fairly then just compensation for the value of the "business enterprise".

c. No resident or business can relocate without knowing: (1) The amount of money available for rebuilding. (2) A definite date the money will be available.

d. Equal grants for business people who have lost income as for residents who have lost shelter.

e. Consideration for the on-going expenses of the business community, such as mortgages, insurance, inventory, debt, etc.

f. Speed. The need to make the above needed information available as rapidly as possible cannot be overemphasized.

2. For the entire community:

a. Compensation for personal property declared contaminated.

b. Compensation from polluters for health problems with strict liability clauses.

c. Lifetime followup of exposed persons. (National registry?)

d. Detailed Federal guidelines to provide consistent, equitable treatment for residences, businesses and local government.

e. Mandatory uniform State Superfund laws to guarantee State government cooperation as well as necessary matching funds.

f. Implementation of extraordinary remedies where such measures are warranted as opposed to taking the "cheapest way out".

These are our recommendations to you. It has come to our attention that Senators Danforth and Eagleton have sponsored legislation which will correct some of these inequities, however, it appears this legislation will not be passed in time for it to help the people of Times Beach. Our people need to come under the provisions you are making for others. We ask that you please amend your bill to include us. The laws need to be changed. Provisions for extraordinary response (such as relocating entire communities as described in Sec. 101, PPH 24) should be implemented where it is warranted, uniform mandatory State Superfund laws should be required nationwide to guarantee necessary State matching funds and a swift response from State officials. Victim compensation must be included for residents and businesses that suffer financial and health losses through no fault of their own. Federal response time must be shortened. Some of these cannot be applied to us; in other areas by amending the Superfund law and making it retroactive to include Times Beach some of our very serious problems can be alleviated.

I have presented here the unexaggerated truth. I feel that the intent of Congress in passing the Superfund Law was not in the areas of response to and compensation in the Federal effort at Times Beach. I ask that you, the committee, consider these facts and make appropriate recommendations to the full Congress. I thank you sincerely for myself and the people of Times Beach for your interest. May God bless each of you.

MISSOURI DIVISION OF HEALTH

RECOMMENDED PUBLIC HEALTH PRECAUTIONS AT TIMES BEACH, MISSOURI
Centers for Disease Control

On December 16, 1982, a private contract laboratory released results of analysis of soil samples which had been collected at Times Beach before the recent flooding had occurred. These results showed two samples with elevated TCDD dioxin levels of 10 and 16 ppb However, today 12-23-82, preliminary data from Environmental Protection Agency contract laboratories have become available for samples which were also collected from Times Beach before the week of the flooding. The data are very preliminary and EPA has not yet had the opportunity to quality assure and verify these data. However, while most results remain in the range of 1 to 20 ppb, two of the first 38 samples showed TCDD levels of greater than 100 ppb. At this point we do not know the extent of areas with these high levels or what has happened to the soil from these more highly contaminated areas as a result of the flooding. It is possible that much of the most highly contaminated soil has been diluted or spread about by the flood waters. It is also possible that isolated highly contaminated areas still exist or have been shifted to new areas. Because of the high degree of present uncertainties, that can only be resolved by further extensive post flooding sampling, the following public health recommendations are made:

1. Non-emergency cleanup activities in Times Beach area should cease. In the unlikely event that emergency activities are necessary, they should be done with full protective gear and only after notification of and consultation with the appropriate federal and state agencies.
2. Residents who have been temporarily relocated are discouraged from moving back into the area.
3. Residents who have already begun to move back into the area are encouraged to leave.

It is recommended that these measures be observed until more extensive post-flood soil sampling and analysis are completed. EPA plans to accomplish these activities within the most rapid time frame possible. For individuals who choose to remain despite these recommendations, the following minimal precautions should be taken:

A. Individuals should limit direct contact with the soil and should not eat, drink or smoke while working in these areas.
In addition, they should wash their hands before any activity which would lead to similar exposures. Also activities which are likely to produce significant amounts of air-borne soil particles should be held to a minimum.

B. Individuals should wear boots which should be thoroughly rinsed off before leaving the area.

C. Coveralls should be worn on-site. If during the course of their activity these individuals should become drenched, the coveralls should be changed immediately. In all cases, used coveralls should be kept in plastic bags apart from all other items to be laundered. Then, all similarly soiled clothing should be dry-cleaned (preferably separate from all other cleaning loads).

D. When direct contact with soil is likely, gloves should be worn. These items should then be cleaned as above or packaged for proper incineration.

E. At this time the use of respirators does not appear to be warranted. However, the use of dust filter masks is encouraged.

F. Individuals should take care to shower and thoroughly wash off adhered dirt after each day's activities with special attention to areas where dirt might accumulate, (e.g., under fingernails).

INTERAGENCY FLOOD HAZARD MITIGATION REPORT

in response to the December 10, 198

Disaster Declaration

(FEMA-672-DR-MO)

Covering

Bollinger, Carter, Cape Girardeau, Franklin, Iron, Jefferson, Lincoln, **Perry, Phelps,** Pulaski, Ripley, Ste. Genevieve, St. Charles, St. Louis, **and Wayne** Counties, Missouri.

This report was prepared by the Region VII Interagency Hazard Mitigation **Team** which consisted of the Following Federal and State Agencies:

←Federal Emergency Management Agency
Department of the Army, Corps of Engineers
Department of Commerce
Department of Housing and Urban Development
Department of Agriculture
Department of Transportation
Department of the Interior
Environmental Protection Agency
Small Business Administration
←State of Missouri, Department of Natural Resources

EXECUTIVE SUMMARY

Purpose of Report

The report and recommendations of the team are intended to provide the framework for Flood Hazard Mitigation during the recovery process and reduce the potential for future flood losses.

Description of the Disaster

On December 6, 1982, the Governor of Missouri requested that a Major Disaster be declared in the State of Missouri, resulting from heavy rains and flash flooding. On December 10, 1982, the President of the United States determined that flood damages within the State of Missouri were of sufficient magnitude and severity to warrant a major disaster declaration under PL 93-288.

The intense early winter storms moved across the State over a devastating five-day period (December 1-5, 1982), causing severe weather, tornadoes, damaging winds, intense rainfall and widespread flooding of major rivers and their tributaries throughout the central and eastern portions of the State. Subsequently, fifteen counties were declared eligible for Individual Assistance: Bollinger, Cape Girardeau, Carter, Franklin, Iron, Jefferson, Lincoln, Perry, Phelps, Pulaski, Ripley, Ste. Genevieve, St. Charles, St. Louis and Wayne Counties. Several counties were also declared for Public Assistance along with individual cities and towns throughout the disaster area.

The most severe damages and hardship occurred in various communities along the routes of the major rivers and streams, such as the Mississippi, Missouri, Meramec and numerous other tributaries. Estimates indicate that over 3000 residences were severely damaged and over 700 were completely destroyed. Early estimates indicated flood crests were equal to or greater than the 100-year flood event, establishing record stages in numerous communities and urban areas.

Six lives were reported lost as a result of these storms, two of which were persons attempting rescue operations for stranded flood victims. Total damage estimates for this disaster are not available, but losses are expected to exceed $100 million.

Preparation of the Report

The Region VII Interagency Hazard Mitigation Team was activated by the Regional Director on December 14, 1982, and a letter of confirmation was sent on December 14 (Appendix 1). On December 16, 1982, the Team Leader requested and the Regional Director concurred to extend the deadline for the submission of this report to 30 days from the date of declaration. This action was needed in order to adequately involve the vast geographical area and the large number of communities in the disaster area.

Recommendations

The major recommendations in this report are for the development of a sound floodplain management program within the State of Missouri, fully staffed and managed at the State level; consideration of a multi-agency approach to acquisition of properties in Times Beach; public awareness campaigns on the severity of flash flood watches/warnings, procedures to follow when they are received, and better dissemination of information to protect the citizens.

Other recommendations of importance are the possibility of a Section 1362 Acquisition Project; allocation goals for funding Section 1362 on a Regional basis; and funding of the U.S. Army Corps of Engineers Lower Meramec River flood control project in St. Louis and Jefferson Counties, Missouri.

Recommendations of significant importance are to finalize "constructive total loss" (CTL) provisions of the National Flood Insurance Program (NFIP); State of Missouri to enact enabling legislation for all counties to join the NFIP; and modification to existing ordinaces for the placing and replacing of mobile homes on pads located in designated floodways when destroyed or removed.

Many recommendations are of an investigative nature, an approach that should allow for a complete analysis of the options and should result in a more comprehensive and reasonable effort for flood hazard mitigation.

Implementation

The lead agency or agencies associated with each recommendation is identified and will be pursued by the team leader for a status accounting for the programs of implementation. FEMA will be responsible for monitoring each recommendation and for completing the 90-day post-flood progress report provides training and other kinds of assistance to local emergency preparedness officials. Local agency dissemination of received warnings, and interpretations of those warnings, are vital to the protection of lives and property. (For example, when a flood crest at 34 fett on the Eureka gage is forecast, what does that mean to a resident of a particular street in Eureka, and to any evacuation route?)

Lead Agency: State Emergency Management Agency (SEMA).

Financing: Minimal.

Schedule: Immediately. Incorporate in State 406 Plan.

7. **Work Element:** Investigate alternative means of inter-agency communication via single-sideband radios and assigned frequences.

Background: During flooding, it is imperative that agencies such as the NWS, the USGS, and the Corps of Engineers share information to keep abreast of flooding developments and flood crest forecasts. During the latest flooding events, the NWS telephone lines were saturated with calls from the public, the news media, and intra-NWS office coordination. The Corps and the USGS experienced difficulty in relaying pertinent data to the NWS and in obtaining the latest flood crest forecasts from the NWS. The Corps is presently equipped with single-sideband radios and assigned frequencies for communicating with their operational projects and field offices.

Lead Agency: NWS, USGS, and Corps of Engineers (COE).

Financing: Purchase of base and mobile single-sideband radios for the USGS, NWS, and COE.

Schedule: FY84 and FY85.

8. **Work Element:** Automate and enhance the rainfall and river stage reporting network to improve the disaster warning capability and maximize lead times.

Background: The NWS issued warnings and statements as promptly and efficiently as was physically possible. [illegible] and enhancement will provide [illegible] time [illegible] to the public.

Lead Agency: NWS, USGS, and COE.

Financing: Ongoing.

Schedule: Immediately.

9. **Work Element:** The Federal Coordinating Officer (FCO) of FEMA, in conjunction with appropriate federal and state agencies, (including the U.S. Army, Corps of Engineers; the Environmental Protection Agency; the Small Business Administration; the Department of Housing and Urban Development; and the State of Missouri, Department of Natural Resources and State Emergency Management Agency) should identify a potential comprehensive plan, programs and sources of funding to acquire and relocate properties of Times Beach, Missouri area. This relocation/acquisition is to [illegible] sound floodplain management practices.

Background: St. Louis County (HUD Entitlement Community) and City of Times Beach should be invited to attend planning and discussion sessions. Precedents for multi-agency cooperation in relocating flood-prone communities in other states exist. The possibility that there are multiple hazards may enhance opportunities for mitigation.

Lead Agency: FEMA Regional Office.

Financing: FEMA as host, providing minutes, etc.

Schedule: As soon as possible.

ST. LOUIS, MISSOURI 63119

MARCH 19, 1983

GENERAL QUESTIONS AND ANSWERS
TIMES BEACH, MISSOURI, RELOCATION PLAN

1. Q. WHAT IS THE FEDERAL GOVERNMENT GOING TO DO WITH TIMES BEACH?

A. AS THE ENVIRONMENTAL PROTECTION AGENCY SAID ON FEBRUARY 22, 1983, FEMA IS GOING TO BUY OUT THE PROPERTY OF THOSE RESIDENTS WHO WANT TO MOVE.

2. Q. HOW WILL FEMA DO THIS?

A. FEMA INTENDS TO SEND ALL PEOPLE WHO OWN REAL PROPERTY, INCLUDING MOBILE HOMES, IN TIMES BEACH A LETTER ADVISING THEM OF THE PROPOSED BUY OUT AND ASKING THEM TO TELL US IF THEY ARE INTERESTED IN SELLING THEIR PROPERTY.

3. Q. HOW MUCH WILL FEMA PAY FOR THE PROPERTY?

A. FEMA WILL PAY WHAT IS KNOWN AS "FAIR MARKET VALUE" FOR THE PROPERTIES AS THEY WERE ON NOVEMBER 30, 1982, PRIOR TO THE FLOOD AND WITHOUT LESSENING THE VALUE DUE TO DIOXIN.

4. Q. WHAT IF I CAN'T AFFORD TO MOVE?

A. AS PART OF THE RELOCATION PLAN, FEMA IS PREPARED TO OFFER ELIGIBLE HOMEOWNERS AND BUSINESSES RELOCATION ASSISTANCE, SUCH AS REASONABLE MOVING EXPENSES, AND HELP IN FINDING A COMPARABLE HOME OR BUSINESS. IN ADDITION, UP TO A TOTAL COST OF $15,000 FOR OWNER/OCCUPANTS FOR ASSISTANCE IN 1) OFFSETTING NEW HOME SETTLEMENT COST, 2) ANY DIFFERENCE IN MORTGAGE RATES, 3) AS WELL AS HELP IN MEETING MINIMUM DIFFERENCES IN COSTS BETWEEN HOMES WHICH WILL BE DECENT, SAFE, AND SANITARY. [SEE QUESTION SEVEN FOR ELIGIBILITY.]

5. Q. WHO WILL BE BOUGHT OUT?

A. GENERALLY, THOSE INDIVIDUALS THAT OWN PROPERTY WITHIN THE CORPORATE LIMITS OF TIMES BEACH, MISSOURI, WILL BE CONSIDERED FOR POTENTIAL BUY OUT.

6. Q. WHO WILL BE RELOCATED?

A. GENERALLY, THOSE PERSONS THAT HAVE BEEN BOUGHT OUT, AS WELL AS THOSE RENTING PROPERTY IN TIMES BEACH, INCLUDING THOSE TIMES BEACH RESIDENTS NOW IN "TEMPORARY HOUSING".

7. Q. WHAT ARE FEMA'S ELIGIBILITY TIME STANDARDS?

A. APPLICANTS CAN APPLY FOR TWO TYPES OF ASSISTANCE:

1)OWNER/OCCUPANTS COULD BE ELIGIBLE FOR BOTH A BUY OUT AND RELOCATION TO COMPARABLE DECENT, SAFE, AND SANITARY HOUSING. TO BE ELIGIBLE FOR RELOCATION ASSISTANCE, THE OWNER/OCCUPANT MUST HAVE OWNED/OCCUPIED THE HOUSE CONTINUOUSLY FROM AUGUST 26, 1982, TO FEBRUARY 22, 1983, OR UNTIL FORCED TO LEAVE DUE TO CONDITIONS BEYOND HIS/HER CONTROL, BUT NOT PRIOR TO DECEMBER 1, 1982.

2)RENTERS GENERALLY WILL BE ELIGIBLE ONLY FOR RELOCATION ASSISTANCE IF THEY OCCUPIED A UNIT UNDER A VALID LEASE IN EFFECT ON NOVEMBER 24, 1982, THAT CONTINUED IN EFFECT UNTIL FORCED TO LEAVE DUE TO CONDITIONS BEYOND HIS/HER CONTROL, BUT NOT PRIOR TO DECEMBER 1, 1982.

8. Q. IF I DONT'T AGREE WITH WHAT YOUR OFFER IS, WHAT ARE MY CHOICES?

A. AS HAS BEEN SAID, THE PROGRAM IS VOLUNTARY SO YOU CAN ALWAYS REFUSE THE OFFER. YOU CAN ALSO ASK TO MEET WITH THE APPRAISER AND DISCUSS YOUR INDIVIDUAL CONCERNS. ANOTHER OPTION IS TO HIRE YOUR OWN APPRAISER TO PERFORM A SECOND APPRAISAL, THEN MEET WITH OUR APPRAISER TO DISCUSS THE DIFFERENCES.

9. Q. HOW WILL ANY BACK TAXES, LIENS, ETC., BE HANDLED?

A. AS WITH ANY NORMAL REAL ESTATE TRANSACTION, THE SELLER IS RESPONSIBLE FOR CLEARING ALL DEBTS ON THE PROPERTY. ALL LIENS AND TAXES WILL HAVE TO BE TAKEN CARE OF PRIOR TO THE TRANSFER OF TITLE.

10. Q. DO BUSINESSES QUALIFY TO BE BOUGHT AND RELOCATED?

A. YES, BUSINESSES ARE GENERALLY ELIGIBLE FOR SIMILAR ACQUISITION AND RELOCATION BENEFITS. THE CRITERIA FOR THE APPRAISAL IS SOMEWHAT DIFFERENT, BUT WE BELIEVE IT IS FAIR AND EQUITABLE.

11. Q. UNDER THE PLAN, WILL YOU PAY FOR THE REPLACEMENT OF PERSONAL PROPERTY?

A. WE WILL GENERALLY NOT PAY FOR PERSONAL PROPERTY INASMUCH AS THE ADVISORY FROM THE CENTERS FOR DISEASE CONTROL AND THE STATE DEPARTMENT OF HEALTH HAVE INDICATED THAT WITH PROPER CLEANING YOU MAY REMOVE YOUR PERSONAL PROPERTY.

12. Q. WILL YOU BUY MY MOBILE HOME?

A. GENERALLY, YES, WE WILL PURCHASE YOUR MOBILE HOME BASED UPON THE FAIR MARKET VALUE, IF YOU MEET THE CRITERIA.

13. Q. SOME MOBILE HOME OWNERS HAVE RECEIVED INSURANCE CLAIMS ON DAMAGE FROM THE FLOOD. IF FEMA BUYS THEM OUT WILL THEY RECEIVE A WINDFALL?

A. NO, THE INTENT OF THE PROGRAM IS TO MAKE EACH RESIDENT WHOLE AGAIN, AS THEY WERE ON NOVEMBER 30, 1982, BUT NOT TO ALLOW ANY WINDFALL PROFITS. ANY INSURANCE PROCEEDS OR SALVAGE AMOUNTS WILL BE DEDUCTED FROM THE FAIR MARKET VALUE PRIOR TO SETTLEMENT.

14. Q. WHAT IF THE OWNER/RENTER OF A POSSIBLE "BUY OUT" IS UNABLE TO PERSONALLY NEGOTIATE THIS OFFER, (i.e., HANDICAPPED, HE'S IN ANOTHER STATE, OR SHE'S AN ABSENTEE OWNER)?

A. FEMA WILL NEGOTIATE ONLY WITH OWNERS AND RENTERS OF GOOD TITLE. HOWEVER, IF SUCH OWNERS SIGN A LEGAL SPECIFIC POWER OF ATTORNEY TO SOMEONE, IT WILL BE RECOGNIZED.

15. Q. WHAT ELSE MUST BE DONE BEFORE FEMA CAN PROCEED WITH THE RELOCATION?

A. PRIOR TO OFFICIALLY BEGINNING THE BUY OUT, FEMA MUST OBTAIN A WRITTEN COMMITMENT FROM THE STATE OF MISSOURI TO TAKE TITLE TO THE LAND, AND EPA MUST PROVIDE SOME ASSURANCES TO THE STATE OF MISSOURI RELATIVE TO THE CLEAN UP. WE ARE HOPEFUL THAT THESE ISSUES WILL BE RESOLVED.

16. Q. HOW SOON WILL WE BE ABLE TO SELL AND MOVE?

A. BUYING AND MOVING A CITY OF APPROXIMATELY 800 FAMILIES IS NOT AN EASY TASK. THIS SUMMER, WE PLAN ON BEING ABLE TO BEGIN MAKING OFFERS TO BUY, AND DEPENDING UPON YOUR RESPONSE, MOVING CAN BEGIN ANYTIME AFTER THAT. FROM NOW UNTIL JULY WE INTEND TO BE STAFFING UP, DOING ALL OF THE REQUIRED TITLE WORK, APPRAISALS, ETC. WE ARE DOING ALL OF THIS FIRST SO WHEN WE START MAKING OFFERS, IT WILL MOVE REASONABLY FAST.

17. Q. WHAT HAPPENS IF I DECIDE NOT TO SELL AND WISH TO REMAIN IN TIMES BEACH?

A. FOLLOWING THE BUY OUT, THE EPA AND THE STATE OF MISSOURI WILL DETERMINE WHAT ACTIONS ARE NECESSARY TO DEAL WITH THE DIOXIN CONTAMINATION IN TIMES BEACH. AT A MINIMUM, YOU MAY BE REQUIRED TO RELOCATE FROM TIMES BEACH TEMPORARILY WHILE CLEAN UP OCCURS. WHAT HAPPENS BEYOND THAT DEPENDS UPON THE LONG TERM USE THE STATE MAKES OF TIMES BEACH. DUE TO THE FLOOD PROBLEM, MOST CONSTRUCTION OF RESIDENTIAL AND COMMERCIAL/INDUSTRIAL BUILDINGS WILL BE PROHIBITED.

18. Q. WILL THE UNUSED MONEY BE DIVIDED EQUALLY AMONG THE REMAINING RESIDENTS?

A. NO, ANY UNUSED FUNDS WILL REMAIN IN THE U.S. TREASURY.

19. Q. HOW MAY I CONTACT FEMA SO THAT ADDITIONAL QUESTIONS MAY BE ANSWERED?

A. FEMA HAS INSTALLED A HOT-LINE "800" AREA CODE NUMBER FOR YOU TO USE IN SEEKING ANSWERS TO YOUR QUESTIONS. THE NUMBER FOR MISSOURI IS 1-800-392-1932. NORMAL OPERATIONS ARE MONDAY THROUGH FRIDAY, 8:00 A.M. TO 5:00 P.M.

Dictionary

COMPLETELY NEW EDITION

^{2}**whittle** *vb* **whit·tling** \ˈhwit-liŋ, -ᵊl-iŋ, ˈwit-\ *vt* **1 a** : to pare or cut off chips from the surface of (wood) with a knife **b** : to shape or form by so paring or cutting **2** : to reduce, remove, or destroy gradually as if by cutting off bits with a knife : PARE — usu. used with an adverb ⟨~ down expenses⟩ ~ *vi* **1** : to cut or shape wood by slowly paring it with a knife **2** : to wear oneself or another out with fretting — **whit·tler** \-lər, -ᵊl-ər\ *n*

whit·tling *n* : a piece cut away in whittling

whit·tret \ˈhwi-trət, ˈwi-\ *n* [ME *whitrat*, fr. *white*, *whit* white + *rat*] *chiefly Scot* : WEASEL

whity *or* **whit·ey** \ˈhwīt-ē, ˈwīt-\ *adj* : WHITISH — usu. used in combination

^{1}**whiz** *or* **whizz** \ˈhwiz, ˈwiz\ *vb* **whizzed**; **whiz·zing**; **whiz·zes** [imit.] *vi* **1** : to hum, whir, or hiss like a speeding object (as an arrow or ball) passing through air **2** : to fly or move swiftly with a whiz ~ *vt* : to cause to whiz; *esp* : to rotate very rapidly

^{2}**whiz** *or* **whizz** *n, pl* **whiz·zes** **1** : a hissing, buzzing, or whirring sound **2** : a movement or passage of something accompanied by a whizzing sound

^{3}**whiz** *n, pl* **whiz·zes** [prob. by shortening & alter.] : WIZARD 3

whiz-bang *or* **whizz-bang** \ˈhwiz-ˌbaŋ, ˈwiz-, -ˈbaŋ\ *n* **1 a** : a small shell of such high velocity that the sound it makes in passing through the air is almost simultaneous with its explosion **b** : a firecracker or similar firework resembling such a shell **c** : ROBOT BOMB **2** : someone or something conspicuous for noise, speed, or startling effect

whiz–bang *adj* : EXCELLENT, NOTABLE

whiz·zer \ˈhwiz-ər, ˈwiz-\ *n* : one that whizzes: as **a** : BULL-ROARER **b** : a centrifugal machine for drying something (as grain, sugar, or nitrated cotton)

who \(ˈ)hü, ü\ *pron* [ME, fr. OE *hwā*; akin to OHG *hwer*, interrog. pron., who, L *quis*, Gk *tis*, L *qui* rel. pron., who] **1** : what or which person or persons — used as an interrogative ⟨~ was elected president⟩ ⟨find out ~ they are⟩; used by speakers on all educational levels and by many reputable writers, though disapproved by some grammarians, as the object of a verb or a following preposition ⟨~ did I see but a Spanish lady —Padraic Colum⟩ ⟨do not know ~ the message is from —G.K.Chesterton⟩ **2** : the person or persons that : WHOEVER **3** — used as a function word to introduce a relative clause; used esp. in reference to persons ⟨my father, ~ was a lawyer⟩ but also in reference to groups ⟨a generation ~ had known nothing but war —R.B.West⟩ or to animals ⟨dogs ~ . . . fawn all over tramps —Nigel Balchin⟩ or to inanimate objects esp. with the implication that the reference is really to a person ⟨earlier sources ~ maintain a Davidic ancestry —F.M.Cross⟩ — **as who** *archaic* : as one that : as if someone — **as who should say** *archaic* : so to speak — **who's who** : the identity of or the noteworthy facts about each of a number of persons

whoa \ˈwō, ˈhō, ˈhwō\ *v imper* [ME *whoo*, *who*] — a command to a draft animal to stand still

who·dun·it \hü-ˈdən-ət\ *n* [substandard *who done it?*] : a detective story or mystery story presented as a novel, play, or motion picture

who·ev·er \hü-ˈev-ər\ *pron* : whatever person : no matter who — used in any grammatical relation except that of a possessive

^{1}**whole** \ˈhōl\ *adj* [ME *hool* healthy, unhurt, entire, fr. OE *hāl*; akin to OHG *heil* healthy, unhurt, ON *heill*, OSlav *cělŭ*] **1 a** (1) : free of wound or injury : UNHURT (2) : recovered from a wound or injury : RESTORED (3) : HEALED **b** : free of defect or impairment : INTACT, UNBROKEN **c** : physically sound and healthy : free of disease or deformity **2** : having all its proper parts or components : ENTIRE, UNMODIFIED ⟨~ milk⟩ **3 a** : constituting the total sum or undiminished entirety of : INTEGRAL **b** : each or all of the **4 a** : constituting an undivided unit : UNBROKEN, UNCUT ⟨a ~ roast suckling pig⟩ **b** : directed to one end : not scattered or dispersed : CONCENTRATED ⟨promised to give it his ~ attention⟩ **5** : seemingly complete or total **6** : having the same father and mother ⟨~ brother⟩

syn WHOLE, ENTIRE, TOTAL, ALL, GROSS mean including everything or everyone without exception. WHOLE implies that nothing has been omitted, ignored, abated, or taken away; ENTIRE may suggest a being completed or perfected; TOTAL implies that everything has been counted, weighed, measured, or considered; ALL may equal WHOLE, ENTIRE, or TOTAL; GROSS implies that customary or expected deductions have not been made **syn** see in addition PERFECT

^{2}**whole** *n* **1** : a complete amount or sum : a number, aggregate, or totality lacking no part, member, or element **2** : something constituting a complex unity : a coherent system or organization of parts fitting or working together as one **syn** see SUM — **on the whole** **1** : in view of all the circumstances or conditions : all things considered **2** : in general : in most instances : TYPICALLY

whole gale *n* : wind having a speed of 55 to 63 miles per hour

whole·heart·ed \ˈhōl-ˈhärt-əd\ *adj* : undivided in purpose, enthusiasm, or will : HEARTY, ZESTFUL ⟨~ effort⟩ **syn** see SINCERE — **whole·heart·ed·ly** *adv* — **whole·heart·ed·ness** *n*

whole hog *n* : the whole way or farthest limit : ALL — used esp. in the phrase *go the whole hog*

whole·ness \ˈhōl-nəs\ *n* : the quality or state of being whole

whole note *n* : a musical note equal in value to four quarter notes or two half notes

whole number *n* : INTEGER

^{1}**whole·sale** \ˈhōl-ˌsāl\ *n* **1** : the sale of commodities in quantity usu. for resale (as by a retail merchant) **2** : a large scale or indiscriminate proceeding — used esp. in the phrase *by wholesale*

^{2}**wholesale** *adj* **1** : of, relating to, or engaged in the sale of commodities in quantity for resale ⟨a ~ grocer⟩ **2** : performed on a large scale esp. without discrimination ⟨~ slaughter⟩ **syn** see INDISCRIMINATE

^{3}**wholesale** *adv* : in a wholesale manner

^{4}**wholesale** *vb* : to sell at wholesale

whole·sal·er \-ˌsā-lər\ *n* : a merchant middleman who sells chiefly to retailers, other merchants, or industrial, institutional, and commercial users mainly for resale or business use

whole·some \ˈhōl-səm\ *adj* **1** : promoting health or well-being of mind or spirit **2** : promoting health of body **3 a** : sound in body, mind, or morals **b** : having the simple health or vigor of normal domesticity **4 a** : based on well-grounded fear : PRUDENT **b** : SAFE **syn** see HEALTHY — **whole·some·ly** *adv* — **whole·some·ness** *n*

whole–souled \-ˈsōld\ *adj* : moved by ardent enthusiasm or single-minded devotion : WHOLEHEARTED

whole step *n* : a musical interval comprising two half steps (as C–D or F♯–G♯) — called also *whole tone*

whole wheat *adj* : made of ground entire wheat kernels

whole wheat flour *n* : [illegible]

whol·ly \ˈhō(l)-lē\ *adv* [ME *hoolly*, fr. *hool* whole] **1** : to the full or entire extent : COMPLETELY **2** : to the exclusion of other things : SOLELY

whom \(ˈ)hüm, üm\ *pron*, *objective case of* WHO — used as an interrogative or relative; used as object of a verb or a preceding preposition ⟨to know for ~ the bell tolls —John Donne⟩ or less frequently as the object of a following preposition ⟨the man ~ you wrote to⟩ though now often considered stilted esp. as an interrogative and esp. in oral use; occas. used as predicate nominative with a copulative verb or as subject of a verb esp. in the vicinity of a preposition or a verb of which it might mistakenly be considered the object ⟨~ say ye that I am —Mt 16:15 (AV)⟩ ⟨people . . . ~ you never thought would sympathize —Shea Murphy⟩

whom·ev·er \hü-ˈmev-ər\ *pron*, *objective case of* WHOEVER

^{1}**whomp** \ˈhwämp, ˈhwómp, ˈwämp, ˈwómp\ *n* [imit.] : a loud slap, crash, or crunch

^{2}**whomp** *vb* : BANG, SLAP

whomp up *vt* **1** : to stir up : AROUSE **2** : to put together esp. hastily

whom·so \ˈhüm-(ˌ)sō\ *objective case of* WHOSO

whom·so·ev·er \ˌhüm-sə-ˈwev-ər\ *objective case of* WHOSOEVER

^{1}**whoop** \ˈh(w)üp, ˈh(w)up, *least frequently for vi 3* ˈhüp [illegible] *vb* [ME *whopen*, fr. MF *houpper*, of imit. origin] *vi* **1** : to utter a whoop in expression of eagerness, enthusiasm, or enjoyment : SHOUT **2** : to utter the cry of an owl : HOOT **3** : to make the characteristic whoop of whooping cough **4** : to go or pass with a loud noise ~ *vt* **1 a** : to utter or express with a whoop **b** : to urge, drive, or cheer on with a whoop **2** : to agitate in behalf of **3** : BOOST, RAISE — **whoop it up** **1** : to celebrate riotously : CAROUSE **2** : to stir up enthusiasm

^{2}**whoop** \ˈh(w)üp, ˈh(w)up, *least frequently for 3* ˈhüp [illegible] **1 a** : a loud yell expressive of eagerness, exuberance, or jubilation — often used interjectionally **b** : a shout of hunters or of men in battle or pursuit **2** : the cry of an owl : HOOT **3** : the crowing intake of breath following a paroxysm in whooping cough **4** : the smallest bit ⟨not worth a ~⟩

whoop–de–do *or* **whoop–de–doo** \ˌh(w)üp-dē-ˈdü, ˌh(w)up-, ˌwüp-, ˌwup-\ *n* [prob. irreg. fr. ^{1}*whoop*] **1** : noisy and conspicuous activity esp. in entertainment, politics, or commercial promotion **2** : agitated public discussion

^{1}**whoop·ee** \ˈ(h)wup-(ˌ)ē, ˈ(h)wü-(ˌ)pē; (h)wü-ˈpē, (h)wü-\ *interj* [irreg. fr. ^{1}*whoop*] — used to express exuberant delight

^{2}**whoop·ee** \ˈ(h)wup-(ˌ)ē, ˈ(h)wü-(ˌ)pē\ *n* **1** : the feverish participation in alcohol-and-sex orgies first widely conspicuous during the U.S. prohibition era — often used in the phrase *make whoopee* **2** : boisterous convivial fun

whooping cough *n* : an infectious disease esp. of children caused by a bacterium (*Bordetella pertussis*) and marked by a convulsive spasmodic cough sometimes followed by a crowing intake of breath — called also *pertussis*

whoop·la \ˈh(w)ü-ˌplä, ˈh(w)üp-ˌlä\ *n* [alter. of *hoopla*] **1** : a noisy commotion **2** : boisterous merrymaking

^{1}**whoosh** \ˈhwüsh, ˈwüsh, ˈ(h)wush\ *vb* [imit.] : to move with an explosive or sibilant rush

^{2}**whoosh** *n* : a swift or explosive rush

^{1}**whop** \ˈhwäp, ˈwäp\ *vt* **whopped**; **whop·ping** [ME *whappen*, alter. of *wappen* to throw violently] **1** : to pull or whip out **2 a** : BEAT, STRIKE **b** : to defeat totally

^{2}**whop** *n* : a heavy blow : THUMP

whop·per \ˈhwäp-ər, ˈwäp-\ *n* [^{1}*whop*] **1** : something unusually large or extreme of its kind **2** : a monstrous lie

whop·ping \ˈhwäp-iŋ, ˈwäp-\ *adj* : extremely large

^{1}**whore** \ˈhō(ə)r, ˈhó(ə)r\ *n* [ME *hore*, fr. OE *hōre*; akin to ON *hōra* whore, *hōrr* adulterer, L *carus* dear — more at CHARITY] : a woman who practices unlawful sexual intercourse esp. for hire : PROSTITUTE

^{2}**whore** *vi* **1** : to have unlawful sexual intercourse as or with a whore **2** : to pursue a faithless, unworthy, or idolatrous desire ~ *vt*, *obs* : to corrupt by lewd intercourse

whore·dom \ˈhōrd-əm, ˈhórd-\ *n* [ME *hordom* sexual immorality, idolatrous practices, fr. ON *hōrdōmr* adultery, fr. *hōrr*] **1** : the practice of whoring **2** : faithless, unworthy, or idolatrous practice or pursuits

whore·house \ˈhō(ə)r-ˌhau̇s, ˈhó(ə)r-\ *n* : a building in which prostitutes are available

whore·mas·ter \-ˌmas-tər\ *n* : a man consorting with whores or given to lechery

whore·mon·ger \-ˌməŋ-gər, -ˌmäŋ-\ *n*, *archaic* : WHOREMASTER

whore·son \ˈhōrs-ᵊn, ˈhórs-\ *n*, *often attrib* **1** : BASTARD **2** : coarse fellow — used as a generalized term of abuse

whor·ish \ˈhōr-ish, ˈhór-\ *adj* : of or resembling a whore : LEWD

whorl \ˈhwȯr(ə)l, ˈwȯr(ə)l, ˈ(h)wər(-ə)l\ *n* [ME *whorle*, *wharle*, prob. alter. of *whirle*, fr. *whirlen* to whirl] **1** : a drum-shaped section on the lower part of a spindle in spinning or weaving machinery serving as a pulley for the tape drive that rotates the spindle **2** : an arrangement of similar anatomical parts (as leaves) in a circle around a point on an axis **3** : something that whirls, coils, or spirals or whose form suggests such movement **4** : one of the turns of a univalve shell **5** : a fingerprint in which the central papillary ridges turn through at least one complete circle

whorled \ˈhwȯr(ə)ld, ˈwȯr(ə)ld, ˈ(h)wər(-ə)ld\ *adj* : having or arranged in whorls; *esp* : VERTICILLATE ⟨~ leaves⟩

whort \ˈhwərt, ˈwərt\ *or* **whor·tle** \ˈhwərt-ᵊl, ˈwərt-\ *n* : WHORTLEBERRY 1

whor·tle·ber·ry \ˈhwərt-ᵊl-ˌber-ē, ˈwərt-\ *n* [alter. of earlier *hurtleberry*, fr. ME *hurtilberye*, irreg. fr. OE *horte* whortleberry + ME *berye* berry] **1** : a European blueberry (*Vaccinium myrtillus*); *also* : its glaucous blackish edible berry **2** : BLUEBERRY 1

^{1}**whose** \(ˈ)hüz, üz\ *adj* [ME *whos*, gen. of *who*, *what*] : of or relating to

South Town Auto Body West, Inc.
905 BLAKEY
TIMES BEACH, MO. 63025

938-5400

July 15, 1983

TO THE MEMBERS OF THE CONGRESS OF THE UNITED STATES

Ladies and Gentlemen:

I think the time has come for government agencies to consider how it's actions affect people. I refer to the quarantine of Times Beach after high levels of dioxin contamination were discovered there.

Our family business was in Times Beach. We started our business in 1959, in a building we leased, in south St. Louis. For twenty years, the income from that business provided us with a nice home, good education for our three children, a comfortable life style, and even a week-end home at a nearby lake. We were a classic example of the American Dream come true! Work hard, invest wisely, and save regularly.

But as the boys grew into men and entered the business, we decided that we needed something better for them. So, in 1979, we obtained a sizable loan, in order to build a modern shop, on a main thoroughfare (I-44) in Times Beach.

The first year was tough! A new location and a failing economy forced us to put $32,000.00 of our savings into the business. But, by August of 1981, we were able to start repaying our loan to the company at the rate of $250.00 a week. And 1982 was our best year since before 1973. Then, on December 5, 1982, a record-breaking flood filled our beautiful building with 8½ feet of water! We thought we were finished, but with the help of good friends and family, we re-opened, just 3 weeks later.

Three days later, the barricades to the city went up, warning people not to enter Times Beach. Our business was ended. 23 years of hard work, careful planning, and our legacy to our children was wiped out. We had no income, our sons had to find employment elsewhere. But the bills still kept coming. Loan payments on the building in Times Beach and on our home, utility bills, living expenses had to be paid. We've been using our savings just to stay alive! There's not much left. My husband is 52 and I am 50. How do we start over again? Our enthusiasm for life is gone. We feel that our lives have been destroyed.

I hope this letter will move you sufficiently to consider amending the Superfund Law, so that we can be reimbursed for the financial losses we have suffered, through no fault of our own. The last seven months have been a never-ending nightmare!

Sincerely,

Marianne Hrin

Marianne Hrin, Sec'y.-Treas.

Mr. James Curtis is the minister at the Full Gospel Tabernacle and also served as city water commissioner. He wrote us as follows:

Dear Sirs:

The following account is given to show some of the additional expenses that have been incurred since our 'voluntary decision' was made to move from Times Beach into government provided housing.

We are aware that dioxin is one of the most controversial issues of recent months and its effect on humans has been the subject of many debates. We are also aware that our only knowledge of dioxin comes from "experts" and therefore we must base our decisions on what the "experts" advise.

In this case the "experts" are the Centers for Disease Control, the Environmental Protection Agency, the Federal Emergency Management Agency, the Department of Natural Resources, etc., et al. Their advice was to move from our homes, not to even attempt to repair them from the flood of December 5, 1982. We aim to show that following that advice has proven to be quite a financial burden.

Some of these expenses are as follows:

A storage unit was rented to store some items we could not fit in the trailers cost $50.00 per month.

Since we have a large family we were provided with two trailers. These trailers were provided with a furnace for heat in winter but we had to provide our own air conditioning for summer. Installation required removal of a whole window unit, and the cost for both air conditioning units was $1200.

Having two trailers requires two billings on utilities. The following figures represent only the amount above a bill paid in Times Beach: Electric $60.00 per month. Water: $18.00 per month. Gas: $50.00 per month and phone $22.50 per month. (Service and equipment only.)

For the six months we have been in temporary housing these figures represent an additional cost of $2253.00.

Following the advice of "experts" to protect our health has not been cheap. I might add that all my income prior to the flood came from within Times Beach. Income from such business ventures as rental property, construction work, Times Beach water commissioner, etc., amounted to about $1200.00 per week. My income now is $105.00 per week from unemployment insurance. Losing my job with the City meant losing health insurance for my family.

A book on the story of our lives would never be salable to the public; the account is too unreal, too fabricated. But the horror of our day-to-day existence is very real.

Remarks made following the flood of December were centered around this thought, "In spite of what we have lost we still have our health".

Seven months later our thoughts echo that we have lost our homes, we have lost our friends of many years, we have lost our church, we have lost our jobs, we have lost our health insurance, we have lost our town, and we wonder if we have lost our health which will agonizingly reveal itself in the next few years or perhaps in the bodies of our children.

My personal goal was to retire this year and reap the benefits of my business. Now, my goal is simply: Make it 'till tomorrow.

Sincerely

(signed) James Curtis

Sherwood Glen Mobile Home Court and Easy Living Mobile Manor represents a total of 337 mobile home spaces and are owned by Mr. Charles Stone.

At the present time there are no lots rented in either park. Mr. Stone also operated a mobile home brokerage firm and a laundromat. Since the closing of the roads he has had no customers for the parks, the laundry or the brokerage firm which dealt in used mobile homes. Taxes, insurance and interest payments continue on as before. The interest on all these enterprizes amounts to over $11,000 per month. Each month he borrows this money.

Based on the fact that an announcement was made that Times Beach people were to be made "whole" again and also that checks would be in the mail by late June or early July, Mr. Stone has closed on property to be used for a new mobile home park. His interest payments are now an additional $6,000 per month.

The cost of building a new mobile home park vs. the cost of his former parks are incomplete at this time but it appears that costs have at least tripled. Zoning laws are more strict now than formerly. Land is not as available, nor is it as level. Escavation in the new location will cost about $250,000. Mr. Stone does not even qualify for the relocation expense for one of these parks.

Melba Perschbacher is the owner of two pieces of commercial property in Times Beach. Both properties were leased. Ten year leases with two 5 year options. Fair market value does not compensate for these leases which represented assured income for the future.

Again, mortgage payments must be made.

As one piece of property is a convenience store located across the street from the mobile home court it is the intent of the owner to relocate at the new mobile home court which is to be built, but it is unlikely that the same interest rate will apply to any new loan and the owner fears that the new buildings "fair market value" will not be the same as "replacement costs".

I would like to emphasize the need for speed in handling any future situations like the Times Beach buy out. The Times Beach buyout was to have been completed by late June. Mrs. Perschbacher's husband, Bill, died on May 13. He had been told by his doctor to avoid stress, yet he lived with the stress of Times Beach for over 6 months. Perhaps if more rapid progress had been made in the buy out, he, Al Kampen, and some of the other heart patients might still be with us. We cannot over-emphasize the strain under which we have all lived and the need to have this stress alleviated as speedily as possible.

Gerald J. Hatcher is the owner of Ill-Mo Bob Cat, an equipment house, renting and selling Bob Cat loaders and Yanmar tractors. The owner of this business advised us that he had received no aid of any kind from any agency. This includes government agencies as well as charitable organizations including the Red Cross and the Salvation Army. Mr. Hatcher says: "The authorities stated on December 23rd 'If you are in the city, get out; if you are out of the city, stay out'".

I moved my business out of the city and the expense of moving and locating in another area was paid by me. At this point the expense is well cover $27,000. The Relocation Brochure for Times Beach gives as top figure of $10,000 for relocation expenses. Mr. Hatcher further stated: "I am at present suffering financial injury because I was forced to move to another location. I am not now as accessible or as visable from the highways in my new location. My customers have not yet found me and some of those who have found me are afraid I will contaminate them".

Laine Jumper is a building contractor who lived in Times Beach. He received a $5,000 grant for replacement of personal belongings. This is the only assistance he has received.

Mr. Jumper has 6 building sites in Times Beach for which he will probably be offered $2000 each, yet the cheapest comparable lots in St. Louis County are in the $13,000 range.

Delay has cost 1½ years at a minimum. He cannot service old customers that are relocating from Times Beach as he has no capital. Small Business Administration loan was refused because he has no business and he cannot have a business without an SBA loan. He had a $30,000 yearly income from rental property and developing real estate. This was the result of working 14 hours per day for the last 5 years. He now feels he must start over and the favorable opportunities he enjoyed 5 years ago no longer exist. Times Beach was unique in that a skilled builder could do all his own wiring, plumbing, masonry, concrete working and all facets of building himself. Times Beach no longer exists. All other municipalities require licensed bonded tradesmen and this adds an additional $15,000 to $20,000 to the cost of a house.

Mr. Jumper has devoted a great deal of time to working and pushing for the buy out. He lobbied for this on State and Federal levels and emphasized that the buy-out include businesses and residences. Now that it is here they are buying out only real estate. He feels the bottom line is that promises made at State and Federal levels are being ignored and forgotten and that is a price most of us cannot afford to pay.

South Town Auto Body West, Inc.
905 BLAKEY
TIMES BEACH, MO. 63025

July 15, 1983

TO THE MEMBERS OF THE CONGRESS OF THE UNITED STATES

Landies and Gentlemen:

I think the time has come for government agencies to consider how it's actions affect people. I refer to the quarantine of Times Beach after high levels of dioxin contamination were discovered there.

Our family business was in Times Beach. We started our business in 1959, in a building we leased, in south St. Louis. For twenty years, the income from that business provided us with a nice home, good education for our three children, a comfortable life style, and even a week-end home at a nearby lake. We were a classic example of the American Dream come true! Work hard, invest wisely, and save regularly.

But as the boys grew into men and entered the business, we decided that we needed something better for them. So, in 1979, we obtained a sizable loan, in order to build a modern shop, on a main thoroughfare (I-44) in Times Beach.

The first year was tough! A new location and a failing economy forced us to put $32,000 of our savings into the business. But, by August of 1981, our business was able to start repaying our personal loan at the rate of $250 per week. And 1982 was our best year since before 1973. Then, on December 5, 1982, a record-breaking flood filled our beautiful building with 8½ feet of water! We thought we were finished, but with the help of good friends and family, we re-opened, just 3 weeks later.

Three days later, the barricades to the city went up, warning people not to enter Times Beach. Our business was ended. 23 years of hard work, careful planning, and our legacy to our children was wiped out. But the bills still kept coming. Loan payments on the building in Times Beach and on our home, utility bills, living expenses had to be paid. We've been using our savings just to stay alive! There's not much left. My husband is 52 and I am 50. How do we start over again? Our enthusiasm for life is gone. We feel that our lives have been destroyed.

I hope this letter will move you sufficiently to consider amending the Superfund Law, so that we can be reimbursed for the financial losses we have suffered, through no fault of our own. The last seven months have been a never-ending nightmare!

Sincerely,

(signed) Marianne Hrin
Marianne Hrin, Sec'y.-Treas.

Robert Fitts owned and rented 9 mobile homes. Only one of the mobile homes was sufficiently covered by insurance that it was paid off after the insurance settlement was received. Mr. Fitts was in the process of making necessary repairs and renovating the remaining eight mobile homes when the roads into Times Beach were barricaded. Now he has no renters for his homes although he has a mortgage payment to make on each of them. In some instances the lending agency is insisting on payments on principal and interest, others are offering some assistance by only requiring payment of interest.

This condition has existed for the past eight months. This is the usual situation. No help for the businessman. Some recognition of this type of hardship is needed.

Jim's Liquor Store is owned by Gary Waltman.

Under present Superfund Laws Mr. Waltman fails to qualify for assistance in all but one category.

Mr. Waltman purchased the liquor store for $50,000. He leased the building and he supported his family from the operation of this store until December 1982. When the streets and roads of Times Beach were sealed off and dioxin contamination caused the people of Times Beach to move elsewhere he had no customers. He then closed his business.

He has been told that the only Superfund or F.E.M.A. category he falls under is a relocation allowance. At best this appears to be $10,000. It can be as little as $2,500. These are the figures quoted in the Relocation Brochure for Times Beach, distributed on June 17, 1983.

Interest on the outstanding indebtedness of this business has continued for the past 8 months and he apparently does not qualify for any other part of the buyout. He has no other livelihood. Even if he gets the top limit of a $10,000 relocation allowance he is still out $40,000.

He had some money which he used as a downpayment on the Times Beach business, however, after the buyout he will not have enough money to buy into another business at someother location.

July 15, 1983

Marilyn Leistner, Mayor
City of Times Beach
Times Beach, Missouri

Dear Mayor Leistner:

You are aware of the dilemma the businesses of Times Beach are in due to the health advisory issued by the Center for Disease Control and Environmental Protection Agency on December 23, 1982 because of the presence of dioxin along the shoulders of the city streets. We would like to share with you how this has affected the small business we own and our lives.

Both of us are former school teachers who invested our entire life savings in a campground franchise of Kampgrounds of America. We were greatly relieved upon the announcement of the buy-out of the residences and businesses of Times Beach because we were facing financial ruin. However, since the buy-out involves buying real estate only and not the business and provides no compensation for economic injury, we will have no income for 1983, therefore no return on our investment for at least one full year. Our income for 1984 and future years will also be reduced until our customers learn where we have relocated.

In addition to loss of income, we have had considerable expense for which there is no compensation. After the flood in December and before the health advisory to vacate the town was issued, we spent approximately $8,000.00 to clean up our campground for reopening. We have spent hundreds of dollars for storage of our equipment and trips to Jefferson City to attend meetings with state officials concerning the Times Beach situation.

In the five years since we bought the campground, after meeting operating expenses, we had reinvested all the income in improvements. We were owner-operators who spent twelve to eighteen hours a day, seven days a week in the operation of our campground. We had developed a very successful campground that operated at capacity for about ninety days a year. Because of this, we had purchased approximately one acre of adjacent land in September 1982 to expand the number of campsites by about twenty per cent. We have lost the potential of this increased income through no fault of our own.

It is impossible to describe the emotional trauma we have experienced in losing the business we have both worked so hard to develop, were so proud of and enjoyed so much. Much of our business was from repeat customers with whom we had developed friendships.

The slowness of the actions of the government agencies in responding to this crisis has added to our financial loss and also greatly increased the emotional stress we have had to endure.

President Reagan has on numerous occasions indicated his support of small business in the United States. We hope that with your urging, the Reagan administration will exhibit their sincerity in this support and compensate us for our loss of business and not just our real estate

We thank you for the time and effort you have spent on behalf of all the citizens of Times Beach and especially the business community.

Attached you will find a statement from our accountant listing our gross income on a monthly basis for the year 1982.

Sincerely,

J.C. Walters

Mr Ronald Reagan
1600 Pennsylvania Ave.,
Washington, D C 20460

Dear Mr President:

We are in a dilemma. We have been told that the businesses and business men would be compensated for our losses, and now we have found out that this is not the fact. Where do we turn now? We have suffered a great loss both monetary and mentally. The government has done well up until now and we give many thanks.

Please re-write the contract with the Federal, State, County, and City Goverments to include us and give some consideration to our needs which are:

Immediate assistance in relocating our businesses and in most instances the relocation allowances will not cover actual costs.

$10,000 cannot possibly compensate for the loss of 6 months or more income. In many instances the businessmen hired employees. Now unemployment compensation charges will be levied against the employer because he laid off his employees. His business no longer operates profitably because of a government ruling. The only acceptable solution to this problem is for the FEMA [illegible] to equitably compensate for the [illegible] of the governments actions.

Yours very truly,

Gary Overton

MEMORANDUM

Date: August 17, 1982
To: Alden Shields
From: Fred A. Lafser
Subject:

Attached is a map indicating locations in Missouri where dioxin has been found. This is the result of a followup investigation that EPA has been doing in reference to the Verona dioxin situation. EPA, in tracking dioxin generated at the NEPACCO facility in Verona, estimates that approximately 153 pounds were generated. 110 pounds have been accounted for.

In 1971-72 Russell Bliss contracted with Nepacco to haul waste oil from their location. During that time period Russell Bliss (who also had contracts with stable owners) would take this waste oil from NEPACCO and transport to his contracted dusting operations and spray this on horse arenas and other dusty areas. This resulted in contamination of four horse arenas. That information will be released tomorrow morning. EPA has just received the documentation of the levels of contamination.

Material was sprayed during 1971 which applied 6 pounds of dioxin at the Shenandoah Stables. Soon after the spraying horses, cats, birds, and mice died. Personnel that were in contact with the material developed signs of dioxin poisoning. CDC recommended removal of the contaminated dirt. That contaminated dirt was removed and located at a fill on Highway 61 adjacent to the stables. The material is covered by Highway 61 and was unable to be sampled. After the original clear up occurred, organic odors were still noticed in the stable. A second clean up activity, again on the Shenandoah properties, took place. Samples of that material indicated 1700 parts per billion (ppb) 2,3,7,8 TCDD (dioxin). Sampling inside the existing horse arena showed levels in the soil surface of 75 to 110 ppb. Dust samples collected on the rafters and bleachers inside the stables indicated 100 ppb.

Another area where dioxin was sprayed was at Bubbling Springs Ranch near Fenton, Missouri. Again illnesses occurred and horses died. Again CDC recommended the material be removed. Unfortunately the materially hauled by

Christopher S. Bond Governor
Fred A. Lafser Director

truck loads at a fill area. This material is currently located at the Minker Residence and fill adjacent to the residence has washed out into Romaine Creek. Levels of dioxin found within ten feet of the Minker residence contained 660 ppb. Levels located in the washed out area between the house and going to Romaine Creek are 900 ppb. Another area that material was dumped from Bubbling Springs Ranch was Stout Trailer near Fenton. Soil sampled at depths of 30" indicated approximately 25 ppb.

The other areas that exist in the state are the Timberline Stables in New Bloomfield which again was strayed and again cleaned up by contractors. Samples of the residual soil showed 53 ppb in the soil and 43 ppb in the dust inside the arena. The contaminated Timberline soil was removed and deposited in the old Jefferson City Landfill. Samples did not show any new detectable amounts in runoff from the landfill.

Bliss Farm in Rosati is also another area where Bliss decreased his load after being overweight. His farm road has shown concentrations of 50 ppb.

Some of this information will be released tomorrow by the EPA. EPA is currently getting some calls on the status of the investigation. We had a meeting with EPA yesterday. Present was Dr. Renate Kimbrough, a dioxin expert, and her assessment of the situation is that any level of dioxin above 1 ppb in these types of situations need to be addressed. She also indicated a significant concern for the accessiblity of these sites to the general public and felt it would be appropriate to limit accessibility if at all possible. There are no standards that can be identified for making this health judgement, and we feel we have to go on the recommendations of experts from the CDC.

EPA will be releasing some information tomorrow indicating the fact that they did find the dioxin and are recommending that these sites have limited access. They are currently looking into the legal options on how they may proceed in taking control of these sites and to clean up (if possible).

DNR is currently acting in a support role in supplying EPA with technical information pertaining to their activities and assisting them in coordinating cleaning up these sites.

In reality, the dioxin announcement will ruin any business that exists at the Timberline and Shenandoah stables and will, in effect, limit public access. EPA and the state's recommendation on the Minker residence is to take as fast action as possible to cap the material and prevent erosion until a disposal option can be developed. Pat Phillips of the Division of Health and Scott Richie of the EPA will be personally meeting with the residents around the Minker site today and informing them of the data and interpreting that data as to how it may affect them. They will also be recommending that they avoid the contaminated area.

To put this into perspective, the levels that were sampled of 25 to 900 ppb should be compared to 37 ppb that existed at Sturgeon where millions of dollars of lawsuits are being won by the workers that were exposed in the cleanup operation; 10 ppb at Seveso, Italy where 730 residents were evacuated and 50 ppt (parts per trillion) in fish where CDC recommends non-consumption of those fish.

Dioxin is a very long lived chemical and will not go away in the near future. There have not been any deaths to our knowledge - but we would not expect such. Dioxin acts as a toxin, carcinogen, mutagen, and fetal toxin and we would not expect to see that many immediate effects.

cc; Chip Casteel

Mr. Dan Maxwell
235 Grove Rd.
Times Beach, MO 63025

Dear Mr. Maxwell:

There has been a considerable amount of reporting on the ABC News Network in the past few months regarding the dangers of the so-called poisonous drug DIOXIN. The United Press Press International (U.P.I.) has been instrumental in bringing these "dangers" to the attention of the general public in the multiple articles it sends to member newspapers. Obviously the ABC is doing the same.

Articles by the news media suggest that Dioxin causes cancer, liver disease, degenerative diseases, miscarriage, birth defects and nerve damage.

The Council on Scientific Affairs of the American Medical Association (AMA), reported on the health effects of Agent Orange and Dioxin contaminants in the October 15, 1982 issue of the JAMA. They stated that Dioxin (TCDD) "is a contaminant", not a "key ingredient" of Agent Orange as reported in the UPI article. A copy of the AMA report is attached.

For 30 years mixtures of chemicals abreviated 2,4-D and 2,4,5-T have been used extensively by home-owners and farmers for ridding lawns and agricultural acreage of unwanted broadleaf vegetation. Similar spray programs have been used in the United States as a means of forestry management. Agent Orange or Herbicide Orange, was the label given by the U.S. military forces to a 50:50 mixture consisting mainly of 2,4-D, 2,4,5-T and varying amounts of the contaminant "Dioxin". These agents were sprayed over certain areas of Vietnam for the express purpose of defoliating the jungle and destroying one the enemy's means of concealment. Also used were Agents Green, Pink, Purple, Herbicide Orange II, Herbicide White, and Herbicide Blue.

Large numbers of persons have been exposed to these herbicides over the past 30 years, in the normal course of employment, in industrial accidents, and of course,in Vietnam. A number of law suits and government regulatory responses are now pending, based on alleged adverse health effects from such exposures. The AMA Council on Scientific Affairs Report states that "There is still little substantive evidence for the many claims that have been made against these compounds".

The most pronounced biological effect of "Dioxin" is its tendency to cause a form of acne called chlor-acne.

The most extensive human experience with the adverse effects of TCDD in man involved the residents of Sevesco, Italy, in July, 1976, when TCDD was accidently released from a chemical plant and a plume of reactor contents rose approximately 60 feet above the factory. More than 37,000 persons were potentially exposed to varying doses.

Two years after the incident occurred, the health effects were assessed. The mild chlor-acne, which occurred mainly in a small group of children, healed quickly. Asymptomatic nerve impairment was reported and there was some liver involvement, but without apparent functional disorder.

The most recent progress report on the residents of the Sevesco area emphasizes the preliminary nature of their findings, but states that except for the skin, no organs or body functions were impaired, no derangement of gestation, no fetal death, no gross malformations, no growth retardation at term, and no cell abnormalities have yet occurred (8 years after the exposure).

So what are the news media, the Environmental Protection Agency (EPA), and the environmentalists so excited about? Is the report of the AMA Council on Scientific Affairs in error regarding the lack of damage that has been done by Dioxin, or are the UPI & ABC reports gross exaggerations of potential dangers? Shouldn't responsible newspapers and radio networks check into this matter? Perhaps you should report to the public what the Council on Scientific Affairs said in its Council Report.

I urge you to look into this matter and check with the AMA Council on Scientific Affairs before any official action is taken in the so-called contaminated areas. Also please try to stop the mis-information.

Very Truly Yours,

E. A. Munyan

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE
PUBLIC HEALTH SERVICE
CENTER FOR DISEASE CONTROL
ATLANTA, GEORGIA 30333
TELEPHONE (404) 633-3311

October 2, 1974

H. Denny Donnell, Jr., M.D.
Division of Health
Missouri Department of
  Health and Welfare
State Office Building
Jefferson City, Missouri 65101

Dear Dr. Donnell:

As you know, the investigation being conducted by the Missouri Department of Health and the Center for Disease Control (CDC) concerning the contamination of horse arena soil by 2,3,7,8-tetrachlorodibenzodioxin (TCDD), has identified a source of distillate residues containing very high concentrations of TCDD. Preliminary toxicologic analyses of these residues here at CDC indicate concentrations of TCDD in the range of 1000 ppm. For the past 3 years, these residues have remained untouched in a storage tank on the premises of Hoffman-Taff of Verona, Missouri, a subsidiary of Syntex Agribusiness, Incorporated. Because of the extreme toxicity of TCDD, we feel that it is important for the public safety that this material be promptly and safely destroyed.

TCDD is a very stable compound which requires incineration at temperatures exceeding 800 degrees centigrade at exposure times exceeding 30 seconds for proper disposal. This incineration should be performed in a properly constructed incinerator capable of achieving these conditions. We recommend utilizing this means of disposal through a reputable service company capable of handling this material in the safest possible manner. Any company contracting for this service should be clearly informed of the nature, concentration, and toxicity of the material in question. Prior to disposal, we would advise that they consult with the Dow Chemical Co., Midland, Michigan, which has had substantial experience in disposing of TCDD-contaminated waste.

Once as much as possible of the tank's contents has been safely and properly removed, we feel that the tank itself should be sealed and deep-buried at a site remote from drainage systems and other potential sources of human exposure and where subsequent unearthing will not occur. Prior to burial, the tank should be carefully sealed and properly marked with respect to its residual contents and toxicity. Other means of disposing of the tank do not preclude the possibility of human exposure either immediately or at some distant point in time. In particular, since TCDD is relatively insoluble and since the residue is a thick, tarry substance, cleaning or decontamination of [illegible]nk does not seem to be a realistic alternative to deep-burial. T[illegible]iate surroundings of the storage tank should be inspected after [illegible]al, and concrete, pipes, or other objects that appear contaminated wit[illegible] esidue should be dealt with in a manner similar to that described f[illegible]k.

[illegible] is not a volatile compound, it can be highly toxic by skin [illegible] Its toxicity cannot be overemphasized, particularly since [illegible]ation in the residue in question appears to be extremely high. [illegible]refore very concerned that all persons involved in the removal of [illegible]aste material be properly informed as to its hazard and that adequate s[illegible] be provided before disposal is attempted. We would appreciate your in[illegible]rming us of any action taken to effect disposal. As you know, the invest[illegible]on in collaboration with your Division is continuing; as in the [illegible]t, we will stay in close contact with you regarding further developments.

Times Beach Chronology: 2 Months Of News About A Troubled City

By Daniel O'Neill
Journal Staff Writer

It has been nearly two months since news first circulated that Times Beach was one of many sites in Missouri being investigated by the Environmental Protection Agency (EPA) for possible dioxin contamination.

In that time, the city has absorbed a cruel combination of natural and man-made disasters that threaten its very existence and have made it the source of local and national news almost daily.

The news has been sometimes confusing, sometimes repetitive and often conflicting. The following is a chonological look at the recent events that have affected Times Beach as they were reported in the local media.

WEDNESDAY, NOV. 10

The *Journal* reports that a list compiled by the EPA reveals Times Beach is among sites to be investigated for possible dioxin contamination. The list, which was not intended to be publicized, includes Times Beach among areas sprayed by an Ellisville waste oil dealer, Russell Bliss, who is known to have purchased waste-oil laced with dioxin.

When contacted by a Times Beach official, Bliss assures the city that no dioxin was in the oil he used to spray Times Beach streets.

WEDNESDAY NOV. 17

The *Journal* reports that an EPA spokesman has notified Times Beach officials that the town is high on the agency's priority list to be investigated for possible dioxin-contamination.

In making the announcement of the notification, Times Beach Mayor Joe Capstick says, "They don't know exactly who has it, but they have to assume that it's possible we have it."

WEDNESDAY, NOV. 24

Local daily newspapers report that federal health and environmental officials considered steps to seal off dioxin-contaminated areas in the state as early as last summer. Plans included evacuation of residents in areas of Jefferson County.

Dioxin was generated from a pharmaceutical plant in Verona, Mo. as an unwanted byproduct in the making of other chemical products such as disinfectants.

Dr. Renate Kimbrough, a spokesman for the U.S. Centers for Disease Control (CDC) in Atlanta, advises that concentrations of dioxin above 1 part per billion parts of soil are, in her opinion, cause for immediate action.

TUESDAY, NOV. 30

The EPA begins testing streets in Times Beach. It is also reported that more than 100,000 gallons of waste oil that may have been contaminated with dioxin were sprayed on most of the streets in Times Beach by Russell Bliss in 1972.

Some Beach residents remember the spraying and recall such things as streets turning purple, a funny smell like paint thinner and birds leaving the area.

WEDNESDAY, DEC. 1

Residents of Times Beach plan a fund-raising drive to hire Envirodyne Engineers Inc., a private firm, to test for dioxin.

Times Beach resident Laine Jumper said "Residents want to know right now whether the dioxin is here. We appreciate what the EPA is doing but they're not fast enough."

EPA officials say that if dioxin is found in the first tests, more tests will have to be taken.

THURSDAY, DEC. 2

An expert on dioxin says residents of contaminated areas need not worry about health effects unless they develop chloracne, a disfiguring skin ailment. Robert A. Neal, president of the Chemical Industry Institute of Toxicology - an industry financed institute that studies toxicological concerns related to the manufacture, use and disposal of chemicals - tells Beach residents that there is "no evidence that dioxin caused long-term health problems."

"If there is no chloracne," Neal said, "one can be reasonably assured that serious illness from exposure is not resulting."

The same day, Russell Bliss says that half the dioxin-contaminated oil he possessed was sprayed on his farm in Rosati, Mo. and at his three horse arenas in eastern Missouri. Bliss says the remainder of the oil was burned as heating oil. "I hope my soul rots in hell if I'm lying," Bliss adds. "It looked like good oil to me."

Health officials describe the form of dioxin produced by the company in Verona - Northeastern Pharmaceutical Co. - as the most poisonous of the 75 varieties of dioxin. Officials call it 150,000 times more toxic than cyanide.

SATURDAY, DEC. 4

Week-long rains continue and officials begin warning of possible high flood waters. Civil Preparedness advises residents of Times Beach to gather their belongings and evacuate the town before flood waters hit. Most residents don't believe the Meramec River will reach the predicted heights and few pay any attention to the warnings.

SUNDAY, DEC. 5

The Meramec River overflows its banks and rages through the area, completely inundating Times Beach. Waters rise up to four feet in one hour and reach record levels. Most people are caught by surprise in Times Beach and virtually every home is damaged or destroyed.

Jef County Journal 1/13/83

WEDNESDAY, DEC. 15

Preliminary tests done by Envirodyne Inc. show that a section of Times Beach City Park contains at least 10 different toxic-waste chemicals. The test was done after Envirodyne was hired by a citizens' group to test other soil samples in the city. Representatives of the company decided to test the park soil after smelling a curious odor in the area.

FRIDAY, DEC. 17

EPA officials tell residents not to jump to conclusions about how much of the town is contaminated with dioxin. However, Art Spratlin, deputy director of air and hazardous material programs at the EPA regional office in Kansas City, expresses fears that the EPA and the city may face an unprecedented cleanup. Spratlin says the "potential is mind-boggling."

Test results by Envirodyne show levels of dioxin up to 16 parts per billion in Times Beach, exceeding the danger level of one part per billion.

TUESDAY, DEC. 21

The EPA announces that three toxic waste sites in Missouri are on its priority list of sites nationwide. The areas are the Shenandoah Stables at Moscow Mills, the Syntex facility in Verona and the Stout and Minker residential areas near Meramec Heights in Jefferson County.

SUNDAY, DEC. 26

The EPA announces that it plans to begin tests in Times Beach to determine how the recent flooding affected contamination in areas of the community. The agency also recommends that residents in Times Beach, driven from their homes by the flood, stay away and that those who have returned to their homes, leave. The recommendation comes after results of preliminary tests by the agency reveal levels of contamination in excess of 100 parts per billion.

Meanwhile, Mayor Joseph Capstick resigns and Alderman Sidney Hammer is named acting mayor.

TUESDAY, DEC. 28

Former mayor Capstick says he believes the EPA and health officials are overreacting to the problem. Many residents voice similar sentiments as they return to their damaged homes. Some flood victims in the area begin receiving disaster relief checks from the government.

Acting mayor Hammer accuses federal authorities of acting too slowly on the dioxin question. Hammer says, "The EPA must think we're a bunch of jerks and country bumpkins." A spokesman for the EPA indicates his office is working as quickly as possible and promises to "pull out all the stops" to solve the problem.

WEDNESDAY, DEC. 29

Nearly 1,000 people turn out at Eureka Junior High School for a hearing held to discuss health problems. They voice anger and criticism at the way state and federal authorities have handled the situation.

State Rep. Bob Feigenbaum tells the crowd he will introduce a bill that will create a state "Superfund" to help clean up the waste.

The Federal Emergency Management Agency (FEMA) announces it will bring a number of mobile homes to the area for those driven from their homes.

THURSDAY, DEC. 30

Despite the possibility of dioxin contamination, Pat Breheny, regional director of FEMA, says officials have decided to haul flood debris from Times Beach because leaving it strewn about the city poses an immediate hazard.

President Reagan orders federal agencies - EPA and FEMA - to give him a report on the Times Beach situation.

FRIDAY, DE

Results of additional soil tests, taken before the flooding, show more contamination. The EPA releases results indicating dioxin levels in several streets and they announce plans to do more testing. Officials also plan to examine residents for correlations between health problems and dioxin contamination.

Meanwhile, plans to remove flood debris are halted until new tests show whether the debris is contaminated.

A St. Louis paper reports that the county police refuse to patrol Times Beach because of the dioxin. City officials had asked the county for police assistance after having to release four city policemen because there was no insurance to cover them.

SUNDAY, JAN. 2

A spokesman for the White House says the president has been briefed on Times Beach and is "continuing to look at the situation."

The state decides to send mental health workers to the city to help counsel residents and help them cope with the strain of the situaton.

WEDNESDAY, JAN. 5

The U.S. Army Corps of Engineers proposes to move the entire town of Times Beach and build a new town on higher ground. U.S. Rep. Robert Young, whose district includes Times Beach, supports the proposal enthusiastically.

Hammer says, "I think it inks. It's one of the dumbest eas and most ridiculous ideas e ever heard. I'm prepared to ht it every inch of the way."

tate natural resources officials suggest that the flood debris be moved to a sanitary landfill and local authorities meet to decide where to take the waste

THURSDAY, JAN. 6

Hammer announces that he could support a proposal by the Corps and Young to build a new town. "Ninety-nine percent of the people would support it if they give us something comparable to what we had," says Hammer. The acting mayor also indicates that the removal of flood debris will begin the next day. The trash is to be hauled to Bob's Home Service, a toxic-waste landfill in Warren County.

Meanwhile, tests show that the highest concentration of dioxin is in a residential area just west and north of the center of town. Test samples that had shown levels above 100 parts per billion were taken from the area on the northeast corner of the city park.

U.S. Sens. Thomas Eagleton and John Danforth call for federal hearings on the dioxin problem and say the "EPA is still dragging its feet in getting the testing teams assembled and on the job."

The previous night, nearly 500 residents met at Eureka Junior High School and vented their anger at delays in the cleanup and the uncertainty surrounding the dioxin. At the meeting Hammer displayed a large map from the EPA depicting the wide extent of the dioxin contamination. The map, derived from tests taken before the flood, shows that most of the city's road beds are dioxin-contaminated with levels ranging from below five parts per billion to more than 100 parts.

Residents of Wright City, where Bob's Home Service is located, express uneasiness about accepting debris from Times Beach at the dump site.

FRIDAY, JAN. 7

President Ronald Reagan orders the formation of a special task force to coordinate flood and dioxin cleanup in Times Beach. Missouri Gov. Christopher "Kit" Bond sent a letter to Reagan stating "I know of no other community that has experienced this magnitude of simultaneous trauma."

The EPA raises questions about toxic levels in flood debris, forcing the state to delay plans to move the debris to a landfill.

Meanwhile, officials in Warren County threaten to go to court to block dumping of the waste in Wright City.

SUNDAY, JAN. 9

Members of Reagan's task force arrive in Times Beach, along with Bond, spurring the start of the long-awaited debris clean up.

Officials order that the debris be loaded into trucks and transported to the hazardous waste landfill in Wright City. Hammer says, "Finally, something is starting to happen" while cautioning that citizens will "take matters into their own hands if the cleanup doesn't continue."

Hammer also makes a plea for the president to come to Times Beach to view the situation first-hand, adding: "If we can't get help from this country, we'll go to another nation for help."

Officials of Warren County obtain a court order from Circuit Court Judge Edward B. Hodge of Warrenton blocking the transfer of the debris to Wright City.

MONDAY, JAN. 10

Tractor-trailer trucks are loaded with flood debris and await the go-ahead to begin transporting the possibly dioxin-contaminated cargo out of Times Beach. The transfer has been temporarily stopped by Judge Hodge's restraining order. State officials say they will try to dissolve the order.

TUESDAY, JAN. 11

Warren County officials are told to post $75,000 bond by 9 p.m. if they wants to maintain the temporary court order blocking the transfer of debris. The restraining order will expire if the bond is not posted. A dozen trucks, piled with debris, wait in Times Beach.

Residents of Times Beach collect more than 500 signatures on a petition asking the president to affect a federal buy-out of their flood-ravaged, dioxin-contaminated town.

WEDNESDAY, JAN. 12

The restraining order blocking the transfer of flood debris from Times Beach to Bob's Home Service in Wright City is lifted after Warren County residents fail to post the necessary bond to maintain the court, order. Trucks loaded with trash begin rolling out of Times Beach by 1 p.m. Tests results show no harmful levels of dioxin in the flood debris.

THURSDAY, JAN. 13

More than 100 people sign a letter asking foreign countries for help in the crisis. Times Beach alderman Harold Goodmon says, "If it will help, the people will sign anything. We're that desperate. We'll declare ourselves a foreign country." Letter organizers say that copies of the letter will be sent to the governments of Sweden, Great Britain, Japan, Australia, Belgium, Canada, Norway, France and the Netherlands.

SATURDAY, JAN. 15

Residents of Times Beach and Warren and Jefferson counties join forces to protest and draw attention to the dioxin problem with a demonstration on I-44. Organizers expect protestors to number more than 1,000.

February 10, 1983

Mayor Sid Hammer
City of Times Beach
Times Beach, Missouri 63025

Dear Sir:

The following directive has been issued to our personnel:

When answering alarms in Times Beach, Absolutely no personnel will enter or approach any abandoned structure which is on fire. Protection exposures will take priority over the involved structure, unless otherwise instructed by the Duty Officer.

No personnel or equipment will enter any area which has been corded off, due to high hazzard, unless it is a life threatening matter. Protective clothing and breathing apparatus will be worn on all fires and incidents in which a high concentration of dust is present. All equipment will be cleaned thoroughly prior to leaving Times Beach and individuals are instructed to take a shower immediately after returning to quarters.

No equipment will enter Times Beach until advised to do so by the Duty Officer. Staging area for equipment will be advised by Duty Officer, if necessary. Up-dates on this matter will be posted as they are received from the E.P.A..

Times Beach, Missouri 63025

Dear Mayor Leistner:

Thank you for writing to Senator Eagleton regarding the problems being experienced by business persons in Times Beach.

I have attached some information regarding Senator Eagleton's efforts to change the Superfund Act to further aid businesses with problems such as you outlined in your letter.

I would be glad to meet with you or any of the business persons in Times Beach to further discuss this problem.

Sincerely,

Mark Van Matre

FRANKLY SPEAKING

WASHINGTON, D.C.

FOR RELEASE
JUNE 20-24, 1983

SOME VICTORIES IN THE FIGHT AGAINST DIOXIN

There has been a lot of news coverage recently about the chemical by-product dioxin; so much so that dioxin is almost becoming a household word. This is a tragic situation, but I am doing all in my power to see that this chemical does not become a Missouri way of life, and that all victims are completely helped.

The spraying of contaminated waste oil that happened statewide in the early 1970's has disrupted the lives of many Missourians. Unfortunately, dioxin is quickly becoming a national nightmare, and it's time that strong measures are taken to ensure that as few people are affected as possible.

In an attempt to improve the situation at one site, the federal governmen under the Environmental Protection Agency's Superfund Act has recently agreed to buy out Times Beach and relocate all the residents of that area. This action is of crucial importance; for this is the first step in helping those who otherwise would lose nearly everything.

As an improvement to this act, I have introduced a bill with Senator Danforth that would further aid victims or businesses that might be forced to close under a health advisory. The Superfund Act currently provides only for the payment of temporary relocation housing for those individuals removed from a hazardous waste area. Our bill would also assume the payment of principal and interest on the business debt of those businesses caught in the evacuation area.

Another matter of crucial importance is the investigation of how, and in what amounts, dioxin affects the human body. In a recent action, the Senate Appropriations Committee earmarked $6 million for investigation of the health consequences of exposure to dioxin and similar chemicals, and for soil research.

In addition, the Committee also adopted language I proposed which will make available the funds needed for medical testing and monitoring of workers who were exposed to dioxin at three St. Louis truck freight yards.

Finally, the town of Sturgeon, Missouri is another site which needs further investigation. The EPA initially did a cleanup there in 1979 after a dioxin spill. Research done immediately after the cleanup showed that no distinguishable amounts of dioxin remained. However, concern has resurfaced that dioxin may still be present in the environment. I have urged EPA to return to Sturgeon immediately to renew the investigation.

Dioxin pollution is a crisis as severe as any that could come from a natural disaster. I am going to see that it is treated as such. All Missourians, whether in Times Beach or at the St. Louis truck yards, can be assured that their health will remain of utmost concern to me.

Our state must remain a safe and beautiful place to live.

STATEMENT BY SENATOR THOMAS F. EAGLETON BEFORE THE ENVIRONMENTAL POLLUTION SUBCOMMITTEE

WEDNESDAY, JUNE 8, 1983

HELP DIOXIN VICTIMS

Mr. Chairman, I am pleased to provide the Subcommittee on Environmental Pollution with my thoughts on S. 1412, a bill to authorize community relocation and business protection in case of toxic substances contamination.

By the most unfortunate set of circumstances, Senator Danforth and I have become somewhat expert on the intricacies of the Superfund Act (Comprehensive Environmental Response Compensation and Liability Act).

It has been a painstaking and frustrating process to watch the Superfund Act be put to its first practical test in meeting a large toxic substances emergency.

As the Subcommittee knows, Missouri has a dioxin crisis on its hands. Currently, there are 31 confirmed sites. An additional 102 sites have been under investigation. Luckily, 75 have been cleared, but new sites are called in for investigation on a weekly basis.

All of the poisoned earth is a result of a hauler of salvage oil, Russell Bliss, who sprayed waste oil to keep down the dust. It is a common practice in many rural areas. The waste oil was spiked with a sludge that Mr. Bliss had been paid a fee to remove from the Northeastern Pharmaceutical and Chemical Company. The spraying occured on city streets, (Times Beach); in trailer parks (Quail Run Park); in residents' back yards (Minker-Stout homes); on stable runs (Shenandoah Stables); in commercial businesses (Baxter-Nurseries); and sometimes truck freight yards (Hall Street Truck Sites). The result is that many of our Missouri residents are innocent victims of toxic dioxin spraying.

These Missouri residents are facing health tests and concerns, some face relocation from their homes, some are having to permanently relocate their families to new homes, and one whole town is being abandoned altogether. All of this is through no fault of the residents.

The bill that Senator Danforth and I have sponsored is an effort to assist victims of toxic waste sites, who are advised to relocate because of the imminent danger. The Superfund Act currently provides for the payment of temporary relocation housing for individuals removed from a hazardous waste area. It does nothing to further aid the victims or businesses, which may be forced to close under the health advisory. This bill addresses this gap in the Superfund Act.

For instance, in Times Beach, Missouri, 30 businesses were forced to close their doors when the news of the dioxin hit. Several months went by before the Environmental Protection Agency reached its decision to buy out the town. In those interim months, businesses were almost forced into bankruptcy because they were unable to pay the bare minimum expenses needed to remain solvent. In some cases, individuals not only were told to move from their homes, but the businesses they worked for were also closed, leaving them without means to support their families. Victims of natural disasters caught in this emergency condition are provided for under the Disaster Relief Act. This bill provides the same kind of assistance for victims of man-made disasters.

Secondly, the bill will provide payment of principal and interest on business debt for those businesses that are caught in the evacuation area. It seems only fair that we try and assist these people in this interim period, so that they have a chance to rebuild their businesses and lives at the end of the disaster.

I am pleased that the Committee has agreed to hear the testimony on this bill today. It shows the commitment that the Senate Environment and Public Works Committee has shown in helping to assure that the Superfund Act is administered in the manner Congress intended when it passed the bill in 1980.

Last week, New Jersey found dioxin sites in Newark. Next week it could be another state. I feel that this bill will help ease the pain of many of our Americans who are instantly caught in the nightmarish experience of our hazardous waste legacy.

ST. LOUIS POST-DISPATCH

FINAL

Vol. 105, No. 4 — WEDNESDAY, JANUARY 5, 1983 — 25¢

Copyright 1983, St. Louis Post-Dispatch

Corps Wants To Build A New Times Beach

By Jo Mannies
and Laszlo K. Domjan
Of the Post-Dispatch Staff

The Army Corps of Engineers wants to relocate the entire town of Times Beach permanently to end future problems with flooding and dioxin contamination.

The corps has proposed that it combine forces with the U.S. Environmental Protection Agency in a big project to build a new town near the current site of Times Beach. The new community would be on higher ground — and on soil free of dioxin.

Under the plan, the highly toxic [illegible] the present town [illegible] be cleaned up.

U.S. Rep. Robert A. Young, D-Maryland Heights, announced the recommendation Tuesday in [illegible]. Young's district includes Times Beach, a community of about [illegible] in southwest St. Louis County.

Young said he enthusiastically supported the proposal. "The residents of this community have suffered enough," he said. "It is time to look at what is best for their future.

"I strongly feel that it would be a far easier task for these people to pick up and move on to a new location than to continue to attempt to fight the incredible odds of trying to clean up and rebuild where they have been living."

Young suggested that the EPA's "Superfund" be used to pay for moving the town. Congress [illegible] up the Superfund as a pool of $1.6 billion to be used to clean hazardous waste. Part of the money comes from fees paid by chemical companies.

Young expressed confidence that he could persuade Congress to approve as much as $[illegible] million in [illegible] money to help pay for relocating the town.

Among residents of Times Beach, the Corps of Engineers plan drew both praise and scorn.

Acting Mayor Sidney K. Hammer said he had heard rumors about the proposal — and disliked what he had heard.

"I think it stinks," Hammer said. "I think it's one of the dumbest and most ridiculous ideas I've ever heard. And I'm prepared to fight it every inch of the way."

He predicted that the town's residents would be about equally divided on the proposal.

Yolanda Bohrer is a resident of Times Beach who has advocated that the government buy all the property in the town. She called the corps idea "one of the best alternatives I've heard."

"It would be good for the residents and everyone else concerned," she said.

Only a few hundred [illegible] have [illegible] to Times Beach since the Meramec River flooded early last

See TIMES BEACH, Page 6

FROM PAGE ONE

[illegible], covering all but one building.

And before the flood, Times Beach had problems with dioxin contamination. The EPA took soil samples from Times Beach just days before the flooding and found dioxin levels as much as 100 times above the recommended "safe" level for human exposure.

Environmental engineers for the EPA were scheduled to start taking soil samples today to determine whether the flooding had affected dioxin levels in the soil.

Young contended that the relocation proposal would be endorsed later this month in a report by the "hazard-mitigation team" set up by the Federal Emergency Management Administration.

That panel is made up of representatives of 10 federal agencies in addition to FEMA and the Corps of Engineers. Its task is to examine the problems caused by the flood and recommend ways to prevent them from recurring.

But Young's prediction was disputed by Patrick J. Breheny, FEMA's regional director and head of the team. Breheny said in an interview after Young's announcement that the relocation proposal would not even be included in the team's report.

"It's fine if the corps and the EPA want to work out something together, but it's not going into the report," Breheny said. "That's because it's not strictly dealing with flood-hazard mitigation."

Rick Alstadt of the Corps of Engineers called his agency's suggestion "a very preliminary discussion on whether or not this can happen." He said the proposal had been made to get the reaction of other federal agencies.

"By combining our authorities, the EPA and the Corps of Engineers could solve the problems of flood control along the Meramec and remove the dioxin," [illegible]

Alstadt is with the Missouri River division of the corps and is the agency's representative on the hazard-mitigation team.

William Hedeman, head of the EPA's Superfund program, said that the proposal to move the n had taken him "somewhat by surprise."

Hedeman said the idea was premature be se the EPA was "just beginning to determ if a contamination problem exists or if it is simp flood-debris problem." If the problems are only du to the flood, only FEMA, not EPA, would be concer ed, he said.

Congressional approval would be needed be re the corps recommendation could be carried out, h id.

FEMA's acting deputy director, Lee M. T mas, also noted that the hazard-mitigation tea was interested only in flooding problems, not dio . But Thomas added that recommendations for rel ating Times Beach residents had een included . the team's reports. Moving a small communit or a neighborhood in a flood plain can be t only permanant way to avoid flooding problems, he d.

Money for relocation might be availab rom federal agencies, including FEMA, Thomas sa That agency recently helped to pay for the relocat of a flood-prone neighborhood in Mobile, Ala., he s

But Times Beach probably would be unab get help with relocation from FEMA becau the community had rejected a federal flo lain ordinance limiting construction in such eas, Thomas said.

A spokesman for Young said the new Time ach would still be "close to the river" that residen love so much."

The $75 million in flood-control money Yo wills seek would include $20 million already aut zed. The money was allocated in 1981 in law deauthorizing the Meramec Dam proposal. ou g's legislative aide, Jim Webb, said Young was c nfident that he could persuade Congress to incre e that authorization by as much as $55 million.

Times Beach is believed to have been contaminated by dioxin in the early 1970s whe waste oil laced with dioxin was sprayed on the town's unpaved streets to control dust. The streets h ve been paved since then.

Dioxin is generated as an unwant the manufacture of certain products, cleansers, pesticides and wood preser highly toxic even in minute concentra hazard posed by the extremely low leve is unknown.

Dioxin can cause a severe skin di chloracne. Tests on animals show that cancer and birth defects and diseases ystem, liver, kidneys and bladder humans are suspected but not proven.

Mr. **Levitas**. Thank you, Mrs. Leistner, for that incredible statement. I think I have been reading and hearing as much about this problem as anybody else in Congress. I am sure there are others who have done as much. But I have never had it driven home to me as poignantly as listening to your presentation, which you described as the unexaggerated truth. I don't know how it could be exaggerated, quite frankly.

Mrs. **Leistner**. Mr. Chairman, I have only touched the tip of the iceberg.

Mr. **Levitas**. That is what I am afraid of. But I do want to thank you for that incredible statement. Your entire statement and attachments will be, without objection, made part of the record.

Before I proceed with a few questions that I have, and perhaps some other members of the committee, I note the presence of our colleague from Missouri, who has been very involved in expressing concern in this area. In fact, he and I had a conversation about this as recently as yesterday. Congressman Richard Gephardt.

I would like to invite Congressman Gephardt to, if he so desires, make a statement. If he also desires, he may join us on the panel here following that statement.

Mrs. **Leistner**. One more thing, Mr. Chairman. I would like at this time to leave with the committee a report prepared by the city of Times Beach that was presented to the President. It talks of dead birds and animals in the city. Also the interim report of the Missouri Dioxin Task Force, which was sent to me last week by the Governor's office.

Mr. **Levitas**. Are those documents already attached to your report?

Mrs. **Leistner**. No, sir, they are not.

Mr. **Levitas**. The subcommittee will, of course, be happy to receive those documents as part of your presentation, and they will obviously then be made part of the record for our use and examination.

Mrs. **Leistner**. Thank you.

[The information received follows:]

CITY OF TIMES BEACH
235 Grove Road
TIMES BEACH, MISSOURI 63025

January 31, 1983

As the governing body of the City of Times Beach, St. Louis County, State of Missouri, we have prepared the following report. In the report we feel you will find what we deem as the most urgent needs of our people.

Our people are the blameless victims of a disaster that is too big for them to handle alone.

Our people have feelings of alienation, helplessness, and confusion which has created a great deal of stress among them.

We feel as good citizens, they deserve respect and prompt help from their government.

We feel, as you read the following report, you will find an earnest plea for help. We have joined together to put forth a united voice to inform our U. S. Senators, State Senators, and State Representatives of the unique and dangerous peril we are now facing.

Our people need and want an immedate buy-out of their property and, if possible, relocation of the City itself so they may be able to stay close by their friends, neighbors, and loved ones.

Our plea is one we hope will be heard and acted upon immediately for the lives of our people depend upon your answer.

May God be with you and lend you guidance in the days to come. Please give us your commitments and your stand on this matter in writing.

Respectfully Submitted

Board of Alderman
City of Times Beach

cc: Gov. Bond, Lt. Gov. K. Rothman, Att. Gen. John Ashcroft, EPA, CDC, FEMA, DNR, Pres. Reagan

Times Beach Chronology: 2 Months Of News About A Troubled City

By Daniel O'Neill
Journal Staff Writer

It has been nearly two months since news first circulated that Times Beach was one of many sites in Missouri being investigated by the Environmental Protection Agency (EPA) for possible dioxin contamination.

In that time, the city has absorbed a cruel combination of natural and man-made disasters that threaten its very existence and have made it the source of local and national news almost daily.

The news has been sometimes confusing, sometimes repetitive and often conflicting. The following is a chonological look at the recent events that have affected Times Beach as they were reported in the local media.

WEDNESDAY, NOV. 10

The *Journal* reports that a list compiled by the EPA reveals Times Beach is among sites to be investigated for possible dioxin contamination. The list, which was not intended to be publicized, includes Times Beach among areas sprayed by an Ellisville waste oil dealer, Russell Bliss, who is known to have purchased waste-oil laced with dioxin.

When contacted by a Times Beach official, Bliss assures the city that no dioxin was in the oil he used to spray Times Beach streets.

WEDNESDAY NOV. 17

The *Journal* reports that an EPA spokesman has notified Times Beach officials that the town is high on the agency's priority list to be investigated for possible dioxin-contamination.

In making the announcement of the notification, Times Beach Mayor Joe Capstick says, "They don't know exactly who has it, but they have to assume that it's possible we have it."

WEDNESDAY, NOV. 24

Local daily newspapers report that federal health and environmental officials considered steps to seal off dioxin-contaminated areas in the state as early as last summer. Plans included evacuation of residents in areas of Jefferson County.

Dioxin was generated from a pharmaceutical plant in Verona, Mo. as an unwanted byproduct in the making of other chemical products such as disinfectants.

Dr. Renate Kimbrough, a spokesman for the U.S. Centers for Disease Control (CDC) in Atlanta, advises that concentrations of dioxin above 1 part per billion parts of soil are, in her opinion, cause for immediate action.

TUESDAY, NOV. 30

The EPA begins testing streets in Times Beach. It is also reported that more than 100,000 gallons of waste oil that may have been contaminated with dioxin were sprayed on most of the streets in Times Beach by Russell Bliss in 1972.

Some Beach residents remember the spraying and recall such things as streets turning purple, a funny smell like paint thinner and birds leaving the area.

WEDNESDAY, DEC. 1

Residents of Times Beach plan a fund-raising drive to hire Envirodyne Engineers Inc., a private firm, to test for dioxin.

Times Beach resident Laine Jumper said "Residents want to know right now whether the dioxin is here. We appreciate what the EPA is doing but they're not fast enough."

EPA officials say that if dioxin is found in the first tests, more tests will have to be taken.

Jeff County Journal 1/19/83

THURSDAY, DEC. 2

An expert on dioxin says residents of contaminated areas need not worry about health effects unless they develop chloracne, a disfiguring skin ailment. Robert A. Neal, president of the Chemical Industry Institute of Toxicology - an industry financed institute that studies toxicological concerns related to the manufacture, use and disposal of chemicals - tells Beach residents that there is "no evidence that dioxin caused long-term health problems."

"If there is no chloracne," Neal said, "one can be reasonably assured that serious illness from exposure is not resulting."

The same day, Russell Bliss says that half the dioxin-contaminated oil he possessed was sprayed on his farm in Rosa[illegible] Mo. and at his three horse arenas in eastern Missouri. Bliss says the remainder of the oil was burned as heating oil. "I hope my [illegible] rots in hell if I'm lying," Bliss adds. "It looked like good oil to me."

Health officials describe the form of dioxin produced by the company in Verona - Northeastern Pharmaceutical Co. - as the most poisonous of the 75 varieties of dioxin. Officials call it 150,0[illegible] times more toxic than cyanide.

SATURDAY, DEC. 4

Week-long rains continue and officials begin warning of [illegible] high flood waters. Civil [illegible] news advises residents [illegible] Beach to gather their [illegible] and evacuate the town [illegible] flood waters hit. Most [illegible] don't believe the Meramec will reach the predicted [illegible] and few pay any attention to [illegible] warnings.

SUNDAY, DEC. 5

The Meramec River overflows its banks and rages through the area, completely inundating Times Beach. Waters rise up to four feet in one hour and reach record levels. Most people are caught by surprise in Times Beach and virtually every home is damaged or destroyed

WEDNESDAY, DEC. 15

Preliminary tests done by Envirodyne Inc. show that a section of Times Beach City Park contains at least 10 different toxic-waste chemicals. The test was done after Envirodyne was hired by a citizens' group to test other soil samples in the city. Representatives of the company decided to test the park soil after smelling a curious odor in the area.

FRIDAY, DEC. 17

EPA officials tell residents not to jump to conclusions about how much of the town is contaminated with dioxin. However, Art Spratlin, deputy director of air and hazardous material programs at the EPA regional office in Kansas City, expresses fears that the EPA and the city may face an unprecedented cleanup. Spratlin says the "potential is mind-boggling."

Test results by Envirodyne show levels of dioxin up to 16 parts per billion in Times Beach, exceeding the danger level of one part per billion.

TUESDAY, DEC. 21

The EPA announces that three toxic waste sites in Missouri are on its priority list of sites nationwide. The areas are the Shenandoah Stables at Moscow Mills, the Syntex facility in Verona and the Stout and Minker residential areas near Meramec Heights in Jefferson County.

SUNDAY, DEC. 26

The EPA announces that it plans to begin tests in Times Beach to determine how the recent flooding affected contamination in areas of the community. The agency also recommends that residents in Times Beach, driven from their homes by the flood, stay away and that those who have returned to their homes, leave. The recommendation comes after results of preliminary tests by the agency reveal levels of contamination in excess of 100 parts per billion.

Meanwhile, Mayor Joseph Capstick resigns and Alderman Sidney Hammer is named acting mayor.

TUESDAY, DEC. 28

Former mayor Capstick says he believes the EPA and health officials are overreacting to the problem. Many residents voice similar sentiments as they return to their damaged homes. Some flood victims in the area begin receiving disaster relief checks from the government.

Acting mayor Hammer accuses federal authorities of acting too slowly on the dioxin question. Hammer says, "The EPA must think we're a bunch of jerks and country bumpkins." A spokesman for the EPA indicates his office is working as quickly as possible and promises to "pull out all the stops" to solve the problem.

WEDNESDAY, DEC. 29

Nearly 1,000 people turn out at Eureka Junior High School for a hearing held to discuss health problems. They voice anger and criticism at the way state and federal authorities have handled the situation.

State Rep. Bob Feigenbaum tells the crowd he will introduce a bill that will create a state "Superfund" to help clean up the waste.

The Federal Emergency Management Agency (FEMA) announces it will bring a number of mobile homes to the area for those driven from their homes.

THURSDAY, DEC. 30

Despite the possibility of dioxin contamination, Pat Breheny, regional director of FEMA, says officials have decided to haul flood debris from Times Beach because leaving it strewn about the city poses an immediate hazard.

President Reagan orders federal agencies - EPA and FEMA - to give him a report on the Times Beach situation.

FRIDAY, DEC. 31

Results of additional soil tests, taken before the flooding, show more contamination. The EPA releases results indicating dioxin levels in several streets and they announce plans to do more testing. Officials also plan to examine residents for correlations between health problems and dioxin contamination.

Meanwhile, plans to remove flood debris are halted until new tests show whether the debris is contaminated.

A St. Louis paper reports that the county police refuse to patrol Times Beach because of the dioxin. City officials had asked the county for police assistance after having to release four city policemen because there was no insurance to cover them.

SUNDAY, JAN. 2

A spokesman for the White House says the president has been briefed on Times Beach and is "continuing to look at the situation."

The state decides to send mental health workers to the city to help counsel residents and help them cope with the strain of the situaton.

WEDNESDAY, JAN. 5

The U.S. Army Corps of Engineers proposes to move the entire town of Times Beach and build a new town on higher ground. U.S. Rep. Robert Young, whose district includes Times Beach, supports the proposal enthusiastically.

Hammer says, "I think it stinks. It's one of the dumbest ideas and most ridiculous ideas I've ever heard. I'm prepared to fight it every inch of the way."

State natural resources officials suggest that the flood debris be moved to a sanitary landfill and local authorities meet to decide where to take the waste.

THURSDAY, JAN. 6

Hammer announces that he could support a proposal by the Corps and Young to build a new town. "Ninety-nine percent of the people would support it if they give us something comparable to what we had," says Hammer. The acting mayor also indicates that the removal of flood debris will begin the next day. The trash is to be hauled to Bob's Home Service, a toxic-waste landfill in Warren County.

Meanwhile, tests show that the highest concentration of dioxin is in a residential area just west and north of the center of town. Test samples that had shown levels above 100 parts per billion were taken from the area on the northeast corner of the city park.

U.S. Sens. Thomas Eagleton and John Danforth call for federal hearings on the dioxin problem and say the "EPA is still dragging its feet in getting the testing teams assembled and on the job."

The previous night, nearly 500 residents met at Eureka Junior High School and vented their anger at delays in the cleanup and the uncertainty surrounding the dioxin. At the meeting Hammer displayed a large map from the EPA depicting the wide extent of the dioxin contamination. The map, derived from tests taken before the flood, shows that most of the city's road beds are dioxin-contaminated with levels ranging from below five parts per billion to more than 100 parts.

Residents of Wright City, where Bob's Home Service is located, express uneasiness about accepting debris from Times Beach at the dump site.

FRIDAY, JAN. 7

President Ronald Reagan orders the formation of a special task force to coordinate flood and dioxin cleanup in Times Beach. Missouri Gov. Christopher "Kit" Bond sent a letter to Reagan stating "I know of no other community that has experienced this magnitude of simultaneous trauma."

The EPA raises questions about toxic levels in flood debris, forcing the state to delay plans to move the debris to a landfill.

Meanwhile, officials in Warren County threaten to go to court to block dumping of the waste in Wright City.

SUNDAY, JAN. 9

Members of Reagan's task force arrive in Times Beach, along with Bond, spurring the start of the long-awaited debris clean up.

Officials order that the debris be loaded into trucks and transported to the hazardous waste landfill in Wright City. Hammer says, "Finally, something is starting to happen" while cautioning that citizens will "take matters into their own hands if the cleanup doesn't continue."

Hammer also makes a plea for the president to come to Times Beach to view the situation first-hand, adding: "If we can't get help from this country, we'll go to another nation for help."

Officials of Warren County obtain a court order from Circuit Court Judge Edward B. Hodge of Warrenton blocking the transfer of the debris to Wright City.

MONDAY, JAN. 10

Tractor-trailer trucks are loaded with flood debris and await the go-ahead to begin transporting the possibly dioxin-contaminated cargo out of Times Beach. The transfer has been temporarily stopped by Judge Hodge's restraining order. State officials say they will try to dissolve the order.

TUESDAY, JAN. 11

Warren County officials are told to post $75,000 bond by 9 p.m. if they wants to maintain the temporary court order blocking the transfer of debris. The restraining order will expire if the bond is not posted. A dozen trucks, piled with debris, wait in Times Beach.

Residents of Times Beach collect more than 500 signatures on a petition asking the president to affect a federal buy out of their flood-ravaged, dioxin-contaminated town.

WEDNESDAY, JAN. 12

The restraining order blocking the transfer of flood debris from Times Beach to Bob's Home Service in Wright City is lifted after Warren County residents fail to post the necessary bond to maintain the court order. Trucks loaded with trash begin rolling out of Times Beach by [illegible]. Tests results show no harmful levels of dioxin in the flood debris.

THURSDAY, JAN. 13

More than 100 people sign a letter asking foreign countries for help in the crisis. Times Beach alderman Harold Goodman says: "If it will help, the people will sign anything. We're that desperate. We'll declare ourselves a foreign country." Letter organizers say that copies of the letter will be sent to the governments of Sweden, Great Britain, Japan, Australia, Belgium, Canada, Norway, France and the Netherlands.

SATURDAY, JAN. 15

Residents of Times Beach and Warren and Jefferson counties join forces to protest and draw attention to the dioxin problem with a demonstration on I-44. Organizers expect protestors to number more than 1,000.

"REPORT ON THE CITY OF TIMES BEACH"

1. WELFARE OF THE PEOPLE:

a. Stress has caused several of our citizens to have nervous breakdowns and heartattacks. There are cases of child abuse, wife abuse, our people are always on edge; in short, our people are leading a non-existing life-style.

b. Symptoms of being exposed to Dioxin (list enclosed).

c. Our children are being harassed, we have numerous cases where our children come home from school and go directly to bed and stay there all day and all night. The laughter is gone from our children; they have no permanent home to go to, they worry about having to move away from friends and school. There is a growing concern in our children about how the Dioxin has affected them--will they be living ten, twenty, or more years from now.

d. Our people are still living in motels, camps, with relatives, and we have some living five or more in one-bedroom houses.

e. A few of our people are still living in Times Beach because they have no place to go; with the fear of what the Dioxin will do to them, they don't allow their children to go outside because of this fear.

f. The Missouri Housing Development Commission and the Federal Emergency Management Agency's proposed housing for our people is disastrous. In order to apply for this housing our people cannot make over $23,000.00 a year or their percentage rate rate will be 12%; on a $42,000.00 home that would mean payments of $400.00 to $500.00 or more, with a large down payment. Also, the lots being offered are outside St. Louis County and out of our school district. There is no way our Senior Citizens can afford even the lowest percentage rate of 4% much less, being eligible for a loan.

g. Any human being needs stability in their lives; our people do not have any--we are in a temporary state of existance with no future to look forward to.

h. Our people are faced with delinquent mortgages and loans they cannot pay. Harrassment from these loan companies and banks because they are unable to make payment. Our property values are -0- because of the Dioxin.

i. The insurance coverage on the people's houses is being cut-off. The people took the advice of CDC and left their homes--now their insurance on these homes is being cancelled.

j. Our businesses lay in ruins; because of the Dioxin, we have over thirty businesses in Times Beach being forced to close their doors.

k. In regards to the Superfund moneys: Our people are being made to feel in order to use the Superfund money to help us, it would be charity and would be a waste on the part of the EPA to use the Fund in this way. As United States citizens and tax-payers we feel that we have the right to expect all the help available from any agency in our Government.

"The American Dream" has been destroyed; our people are beyond the breaking point; we need immediate answers and committments now--we will not last much longer--our plea is for our people and our children. Please bring back the smiles and the laughter of our children; now there are only tears of sorrow. Our children's lives and happiness are important to us.

2. THE CITY OF TIMES BEACH (GOVERNMENT):

   a. Financially our City is broke we cannot meet our debts, fix our road, water systems, or repair our city buildings.

   b. There is no financial aid for our city because of the Dioxin and being in a Flood Plain.

   c. Lay-offs of our City personell has begun; as well as our Police officers, because funds are not available to pay them.

   d. Our City will not be able to hold on much longer, and we need answers and committments now.

3. IN THE YEARS TO COME (FUTURE PROBLEMS):

   a. Will our people because of the Dioxin be able to get any type of Insurance Coverage?

   b. Will our people have the Medical Assistance they need in the future?

CITY OF TIMES BEACH
235 Grove Road
TIMES BEACH, MISSOURI 63025

[illegible] January 31, 1983

The following accounts can be verified by neighbors, relatives, and medical records:

In one block of Grove Street live only two families. This particular block was found to have well in excess of 100 ppb's of dioxin.

In the first family these problems are noted: The husband had complicated illnesses which included 70% loss of hearing, lapse of memory, blood disease, and severe hardening of the arteries which brought on a fatal stroke. He died 2½ years ago. It is also noted that he had large clusters of blackheads around his eyes, ears, and mouth that when agitated became extremely sore and bloodshot. The wife presently suffers from a severe skin disorder in the palms of her hands which leaves them very dry, cracked, and often bleeding.

Of the second family: The wife suffers from a similar skin condition. She also has 80% loss of hearing and a lapse of memory. She has kidney problems, and an uncharacteristic feebleness that she has required hospitalization at least six times in the past two years. The husband has also been hospitalized several times in the past two years and presently suffers from leg problems and a stomach disorder.

It is also known of several deaths of small animals in a one block area. These include at least nine dogs which died in very similar ways. These dogs, normal and healthy, grew to be several weeks old: all were active and ahd good appetites. Suddenly, each in isolated cases lost all appetites, would not move unless helped, would bleed at the rectum, and finally died. These pups; four out of five of one litter, four dogs of a neighbor, and one dog of another neighbor were born at different times yet showed common problems.

In the same area, many dead birds were found. Many of the squirells were found dead, and those as well as some which were seen about ready to

> die, would have no hair on their tail or body.
>
> One man who lives on another street found to contain over 100 ppb dioxin, has also had major medical problems requiring hopitalization and surgery. He also reported finding a great many birds in his yard dead or dying. For a while he would gather them up and burn them with his trash. One day he called the Humane Society about the problem and they requested he catch some of the live birds and they would take them for testing. He caught three and called the Society back, but they never came for the birds; so they died and he disposed of them as well.
>
> Finally, the account of a young family living on another "hot" street and often walked to church; which is on another "hot street". The husband, 29, has been told by his doctor that his kidneys and liver are in the condition of what he would expect to find in a much older man who had smoked and drank for a long time. Having been quite active in a church which teaches against both, he has neither smoked or drank. The wife, 25, has in the past two weeks undergone a radical mastectomy which doctors said is extremely rare for a young lady of her age and coming from a family with no history of breast cancer. The daughter, 4, has a bladder condition as well as a skin problem.

As stated at the outset, all of this can be verified by neighbors, relatives, and medical repor .

December 28, 1982

TO: Officials of the United States Government

From: Gerald J. (Jerry) Hatcher

Horace Greeley said, "The way to do things is to begin". I am beginning!!

I am a United States citizen, Missourian, Businessman of Times Beach for 12 years and a voting taxpayer. I have located a business in Times Beach by choice, and have lived outside Times Beach by choice. I have had no vote in what the town wanted to do about business license fees, road repairs, utility taxes or flood insurance. I have complied with the wishes of the town, because of their vote. I feel that I have been delt with fairly by the town authorities.

Now that dioxin has been discovered, I find the government says not to help anyone who didn't vote for our programs! Kick them, keep them down and let our United States citizen, Missourian, Businessman and voting taxpayer save himself. Don't help, unless he wants to relocate. He didn't like our programs, so let him sink. I will not sink!! But, I will remember!

If I lived on the coast of the U.S. of A., and had to face all of the disasters they face there, would I be asked to relocate or be denied a loan? There seems to still be people there! I do not feel that the government is looking out for the good of its citizens when they will not give a loan to a citizen to rebuild their homes or businesses, but will give to foreign governments that repay poorly or never! THAT money comes from the United States citizen, Missourian, Businessman and voting taxpayer.

Whether the government realizes it or not, the people in Times Beach lived here for reasons not much different than people living in New York, Miami or St. Louis. This is where they want to live or do business! What we need is not how to tear down the lives of the people in Times Beach, but how to build them up. LOANING not giving is a self help program.

A large automobile manufacturer was loaned USA dollars that they paid back. That company is a group of people! I would not be too surprised if the people at that company voted against some government programs that they didn't like, but they got a loan!

Times Beach is a town that needs USA dollars. Why don't they get a loan? No loans for people voting against a government program! They are a small group of USA people. Is that why, small? I have read where Times Beach is a mistake. Times Beach is not a mistake! It is a group of people that will survive! They will vote, work, pay taxes and continue to know what caring is all about! I am not sure about the U. S. Government and the elected officials or some of the other citizens that live in their ivory towers!

Jan. 18, 1983

Dear Mr. President:

Please give this letter your immediate attention! We are in a crisis situation and cannot wait any longer for a solution.

I am writing this letter to charge the Environmental Protection Agency as being directly responsible for destroying business in Times Beach, Mo.

On December 5, the horrible chain of events began when our building was filled with 8 feet 4 inches of flood water. We stood on the highway (I-44), taking pictures, with tears streaming down our faces - 23 years in business, a lifetime of hard work, destroyed by the flood!

On December 7, when the flood waters had receded, my husband and our two sons went to see the damage that had been wrought by the flood. The sight that met their eyes was far worse than their greatest expectations. Our beautiful office and reception area was totally destroyed. The suspended ceiling was ripped down, cabinets and their contents were torn off the walls, the paneling was bulged out from the weight of the saturated insulation, all the equipment (tire changers, wheel balancer, paint mixing equipment, grinder, buffers, adding machines) were covered with mud. About four inches of mud and slime covered the floors, the 8 ft. cyclone fence and gate which enclosed the entire parking area was forced to the ground by the force of the water. The possibility of restoring our business to a operable state seemed like too monumental a task to even attempt. And yet, what was the alternative? We had too many years of hard work and money invested in this business. We still owe $75,000.00 on the loan for the building and $6,000.00 on the frame rack. We've put over $40,000.00 of our life's savings into this business. My husband and our two sons derive their income from this business. We have house payments and utility bills to pay every month.

So, with the help of numerous friends and members of the family, the monumental task began. They worked 10 hours a day, seven days a week for three weeks - cleaning out the mud, hosing off the equipment and drying it off, getting as much of the equipment as possible back in operation. Finally, on December 27th we hung out our sign to announce, "YES - WE ARE OPEN!" Our spirits were high and we felt that we had come through this terrible disaster in pretty good fashion. We called in jobs that had been scheduled for the week the flood hit. Our customers told us that they would wait until we re-opened, rather than take their cars somewhere else to be repaired. People were coming in for estimates, ordering tires, and things were looking pretty optimistic! And we did it all ourselves! During the flood disaster, much assistance was given to the residents of Times Beach from federal agencies, state agencies, the Red Cross, the Selvation ARmy and numerous charitable and community organization. Nothing was offered to the businesses that were flood victims! Nothing but Small Business Loans at 8% interest. We figured we didn't need any more loans, we already owed enough money. Business has been totally ignored during this whole crisis!

On December 30, the final blow came! The city put up road blocks at all entrances to the city, at the suggestion of the E.P.A. The E.P.A. had ordered all residents to leave Times Beach and ordered the general public to stay out of Times Beach because of possible toxic contamination. The next few days were like a nightmare! Every local newspaper had front page pictures of the ominous signs, showing a skull and crossbones and large block letters stating: "DANGER - DO NOT ENTER - POSSIBLE TOXIC CONTAMINATION". Every television station headlined their newsreports with the signs and the story. As the days went by, the news of dioxin contamination in Times Beach was getting national coverage.

THE DAY THAT THE SIGNS WENT UP, OUR BUSINESS CAME TO AN ABRUPT HALT!!!

Insurance agents, who regularly recommend us to their customers, told us that they had sent at least ten (10) people to us for estimates! But they came back with estimates from other shops, expressing a fear that they might jeopardize their health by coming into Times Beach! And really, who could blame them?

But just how dangerous is the dioxin contamination? The tainted oil was sprayed on the roads in 1971, and, as far as I know, their is no documented evidence that anyone here has suffered from exposure to this supposed contamination. In fact, no evidence has been given that anyone, anywhere, has suffered from exposure to dioxin contamination. EPA has no answers for us! Anytime they are present at a meeting or interviewed by the media, all they have said is, "We really don't know what the effects of exposure to dioxin have on human life." So, why the terrorist tactics? Why the isolation of an entire city? Why the signs with skull & crossbones? Why the men dressed in white coveralls and respirators? Believe me, the psychological damage done to the people of Times Beach by the EPA is far worse than the exposure to dioxin has been. The psychologic damage is evident on the faces and in the voices of everyone here. We have no direction. We have no defense against this disaster. We are confused. We are prone to burst into tears, for no specific reason. The frustration is unbearable.

But the damage is done and irreversible. The general public has been terrorized and Times Beach has been stigmatized. No matter what the EPA test results show, our business in Times Beach is finished.

The EPA is directly responsible for the loss of our business and must be held responsible for restitution for that loss ! BUY OUT is the only answer and we can wait no longer. If no money is forthcoming by FEBRUARY 1st, we will be forced to close our doors and file for bankruptcy. Five more people will join the ranks of the unemployed. Time is of the essence! We must have ACTION NOW!

Please respond to this letter at once.

Sincerely,

Marianne Hrin, Secretary-Treasurer

P.S. I am enclosing a letter, giving a short history of our business and pictures of the flood and the EPA damage.

ILL MO bobcat P.O. BOX 600 • EUREKA, MISSOURI 63025 • (314) 938-5770

For 11 years, I have owned an equipment dealership in the City of Times Beach. I would like to help you understand the problems incurred by someone involved with a City that has been flooded and contaminated by dioxin. The City of Times Beach voted against Federal Flood Insurance and must pay the consequences of the decision. I did not have a voice in the voting, because I chose to live elsewhere. I lost economically, the same as they. I am not concerned, nor do I ask for consideration from anyone, as a result of the flood.

I need help with the dioxin contamination problem. This is a man-made problem that I cannot control! I have been forced out of my building and off land where I normally do business. Because of the C.D.C. statement on December 24, 1982, no one will come into my place of business. S.B.A. informs me that they will loan money, but the land in Times Beach must be sold. If I can't do business there, how can anyone else? I have to pay rent for our alternate location, the loan payment on the original building and a new loan means more payments, combined with the extra expense of a forced move! The residents of Times Beach have been helped to relocate. The Government will give business establishments no such help! However, I could lose it all because I don't have a viable business, due to the dioxin statement by C.D.C.

I was refused a hand shake by a customer, because he felt I'd contaminate him! This may not seem to cause an economic impact, but if one thinks about not shaking the hand, he may not want to buy the equipment! Another customer wanted to make sure I had no dirt on a machine or truck when it was delivered!

I certainly do not know the answers, but know we must have one!

Sincerely,

ILL-MO BOBCAT, INC.

Gerald J. Hatcher
President

GJH/jd

INTERIM REPORT OF THE MISSOURI DIOXIN TASK FORCE

submitted to
Governor Christopher S. Bond

JUNE 1, 1983

June 1, 1983

Honorable Christopher S. Bond
Governor
State of Missouri
State Capitol
Jefferson City, MO 65101

Dear Governor Bond:

I hereby convey to you the interim report of the Dioxin Task Force as requested in your executive order 83-5.

Since its inception in February of this year, the task force has studied the volume of information on dioxin presented in papers and speeches by experts in the field. The recommendations in this report reflect that study.

The task force appreciates comments on this report as well as further guidance on the final report or any other matter you wish the task force to address.

Respectfully submitted,

James A Finch

James A. Finch, Jr.
Chairman
Governor's Dioxin Task Force

JAF:brd

PREFACE

Explanation of Terms

This report deals with one extremely toxic member of a class of compounds commonly called "dioxins". Within the 75 possible chlorinated dioxins, there are 22 isomers of tetrachlorodibenzo-p-dioxin (TCDD). In Missouri, the contamination is almost exclusively with one highly toxic member of this family, the member "2,3,7,8-TCDD". For simplicity and unless otherwise stated, this report uses the terms "2,3,7,8-TCDD", "TCDD", and "dioxin" interchangeably, all referring to one member of a family of compounds.

EXECUTIVE ORDER
83-5

WHEREAS, extensive laboratory testing has confirmed the presence of dioxin at several locations in Missouri; and,

WHEREAS, dioxin is a potentially deadly chemical which threatens the health and safety of thousands of Missourians,

NOW, THEREFORE, I, CHRISTOPHER S. BOND, GOVERNOR OF THE STATE OF MISSOURI, by virtue of the authority vested in me by the Constitution and laws of Missouri, hereby establish the Governor's Task Force on Dioxin (hereinafter the "Task Force") which shall be composed of such residents of Missouri as from time to time may be appointed by the Governor. The Task Force shall include representatives of Missouri higher education institutions and Missouri companies which have expertise regarding hazardous wastes, as well as concerned citizens. The Chairman of the Task Force shall be designated by the Governor.

The purposes of the Task Force shall be as follows:

1. To examine and evaluate all known methods, processes and technologies for the destruction and containment of dioxin, particularly with respect to dioxin as it exists as a contaminant in soil and stream sediment at various locations in Missouri;

2. To examine and evaluate the public health dangers associated with dioxin, particularly with respect to dioxin as it exists as a contaminant in soil and stream sediment at various locations in Missouri;

3. To prepare and present, not later than June 1, 1983, an interim report which, inter alia, provides specific recommendations for solving those public health and environmental problems occurring in Times Beach, Missouri which are the result of dioxin contamination exacerbated by widespread flooding; and

4. To prepare and present, as soon as practicable but not later than October 1, 1983, a final report which includes the evaluations set forth in paragraphs 1 and 2 above, and which recommends a practical and effective plan of action for implementing comprehensive and permanent solutions to the public health and environmental problems caused by dioxin contamination in Missouri.

The Director of the Department of Natural Resources and the Director of the Division of Health shall make available such staff and support resources as are needed by the Task Force in the course of its deliberations. All meetings of the Task Force shall be open to the public, and a record shall be kept of all Task Force proceedings.

EXECUTIVE ORDER
83-5
Page 2

Members of the Task Force shall receive no compensation for their services, but shall be reimbursed from funds provided through the Department of Natural Resources for their reasonable and necessary expenses. The Task Force may contract for the services of such consultants and experts as it deems necessary and shall pay for such services from funds provided through the Department of Natural Resources or the Division of Health.

The Task Force shall meet at the call of the Chairman, or at the call of the Governor or his designate, and shall dissolve upon the issuance of its final report, unless extended by subsequent Executive Order.

IN TESTIMONY WHEREOF, I have hereunto set my hand and caused to be affixed the Great Seal of the State of Missouri, this 14th day of February, 1983.

Christopher S. Bond
GOVERNOR

ATTEST:

James C. Kirkpatrick
SECRETARY OF STATE

GOVERNOR'S DIOXIN TASK FORCE

The Honorable James A. Finch, Jr.
Judge
Chairman, Governor's Dioxin Task Force

Mr. Dwight Douglas
Douglas, Douglas & Johnson Law Offices

Mr. Ray Forrester
Engineering Manager & Dioxin Project Supt.
Syntex Agribusiness, Inc.

Dr. Perry King
Director, Quality Assurance Chemicals
Mallinkrodt, Inc.

Dr. Robert L. Powell
Assistant Professor of Chemical Engineering
Washington University

Dr. Carl J. Marienfeld
Professor of Family & Community Medicine
Environmental Health Surveillance Program
Sinclair Research Farm

Mrs. Sharon Rogers
Warren Countians Against Hazardous Waste

Dr. George Roush
Director, Dept. of Medicine & Environmental Health
Monsanto

Dr. James Shaddy
Associate Professor of Ecology
Northeast Missouri State University

Mrs. Betty Wilson
Environmental Quality Chairperson
League of Women Voters

TASK FORCE STAFF SUPPORT

Department of Natural Resources

Fred Lafser, Director
Ronald Kucera, Deputy Director

Robert Schreiber, Director - Division of Environmental Quality
Linda James, Assistant Director

David Bedan, Director - Waste Management Program
Joe Jansen, Environmental Engineer
Beth Rice, Environmental Engineer
Dan Tschirgi, Environmental Engineer
Dianne Luebbert, Clerk Steno
Martha Siegel, Clerk Typist

Mary Still, Director - Office of Public Affairs, Division of Management Services
Nancy Guyton, Office of Public Affairs

Department of Social Services

Dr. Robert Hotchkiss, M.D., Director - Division of Health

Dr. Denny Donnell, M.D., MPH, Director - Disease Prevention Section
Dr. Patrick Phillips, DVM, MSPH
Dr. Thomas Satalowich, DVM, MSPH
Jeff Staake, Dioxin Activities Coordinator

Governor's Remarks
Dioxin Task Force Meeting
February 23, 1983

Judge Finch, Members of the Task Force, Ladies and Gentlemen:

Let me extend first of all my warm welcome and my sincerest thanks to all of you who have agreed to serve on the task force. We've brought this distinguished group together to assist us in solving what has become to be Missouri's most serious challenge we face in the environment today. That is, of course, ridding our environment of dioxin, a deadly chemical which threatens the health and has disrupted the lives of many Missourians. I am most grateful that you've accepted this challenge to serve on the task force. It is a very timely meeting that we have today and there is much work to be done. As Fred indicated, as you know, yesterday the EPA and the federal task force on Times Beach proposed a buy-out for the residents of the Times Beach area. We are hoping also to have a similar conclusion to the Minker residence site, which will enable us to get to work immediately on the most pressing and most immediate problem, that is moving people from the sites from direct contact with dioxin or the likelihood of it. It will enable you to concentrate on the scientific responses which we must make on a longer term basis to the problems of dioxin. During the past few months, obviously, we have been bombarded with a great deal of information on this deadly chemical and what it means to the residents of many Missouri communities. I've had the opportunity over the last several months to visit personally with the people whose lives have been disrupted, whose families have been subjected to a great deal of concern over the presence of dioxin and to their fears as to what it might cause them in the future in the way of health and other problems.

In southwest Missouri where much of the dioxin was produced citizens are fearful there, however, on a continuing basis. Their streams and waterways may have been contaminated threatening wildlife, fish, as well as the health of area residents. In this area of the state where tourism is so very important we have to take strong action to ensure that clean waterways will continue to provide us with abundant fish, wildlife, and water supply. The people of southwest Missouri know that we are doing everything possible to protect the natural surroundings while we look for a way to remove permanently the threat of dioxin from their environment.

Or eastern side of the state, as you well know, families have been told to leave their homes to protect themselves from the health hazards of dioxin contamination in their yards and the streets of their communities. Gardens where once vegetables grew and children played are now empty because the fear of dioxin contamination has made citizens fear for their health and the health of their children in particular.

I believe the time has come for us now to provide some straightforward answers and a plan of action to combat the presence of dioxin in a way that will lower public anxiety and lead to some long-range permanent solutions. We were all very much relieved, as I indicated earlier, to hear that the residents of Times Beach will be offered a buy-out from the federal government. Yesterday I met with the leaders of the Missouri General Assembly to ask them for their approval and I've also asked the Missouri Legislature to provide our share of the cleanup and relocation expenses. The action at Times Beach and what we hope will occur at the Minker residence site should help relieve the human suffering that these families have endured. Still, other families at other sites, discovered and yet to be discovered, await the answers that I hope this blue ribbon task force will find. That is a way to remove permanently the dangerous levels of dioxin from the soil in Missouri and to control dioxin where it is present in levels above that which is safe.

Let me provide you with a brief recount of the events which led up to our current situation. Let this be helpful for background for you and give you context within which to place your considerations. Fred Lafser and his staff will be providing you with more details on the work of the Department of Natural Resources. Dr. Hotchkiss will be giving you briefings on the health aspects and the determinations by the federal government, in particularly the Centers for Disease Control. Also, you will hear from Mr. Rice with the comments on the role of the Environmental Protection Agency, what they have done and what they seek to do in the future.

You might recall that last year, last December actually, after months of wrestling with this problem and sometimes making successful advances with the federal government and sometimes not, I went to Washington and met with top EPA officials personally and that meeting gave us the information that we needed to protect the health and safety of people in the Jefferson County area who had been exposed to dioxin contamination. We finally learned that the EPA's tests showed there that the levels of dioxin at the so-called Minker residence site were in sufficient quantities that the health experts believed that they were significant risks to the people living there. On December 8, I ordered that the state offer temporary relocation assistance to the families at the Minker site and the Division of Health was ordered to begin medical evaluations of the individuals who may have been exposed to the dioxin. I also reiterated my requests at that time that the EPA Superfund be used to find a permanent solution to the contamination of these areas and we requested that the EPA accelerate its testing process on samples from the sites identified potentially as dioxin sites throughout the state of Missouri.

After that as you well know the heavy rains of December added another and even more volatile dimension to the dioxin problem. Times Beach, the site of EPA testing for dioxin on road beds, had been virtually destroyed by severe flooding, 100-year floods which afflicted that area. As the flood waters were receding on December 23, just about Christmas Eve, the U.S. Department of Health and Human Services Center for Disease Control in Atlanta advised us that the pre-flood test samples of the Times Beach areas showed levels of dioxin that could be dangerous. The CDC recommended because of the uncertainties left behind in the mud and debris from the flood that non-emergency cleanup activities in Times Beach cease, that residents who had temporarily relocated stay out, and that residents who had already begun to move back in, leave. That day at my request the EPA agreed to send in new testing teams to conduct post flood dioxin tests. The federal Disasters System Center in Fenton, Missouri agreed to reopen on December 27 and stay open as long as necessary to help the Times Beach residents relocate. I then directed our Department of Public Safety, Division of Health to go back to Times Beach and assist with law enforcement and public health activities.

Since that time state officials have been working as they could with a variety of federal and local officials who assist with relocation plans, test sampling, and cleanup activities. As we developed a solution to the flood debris problem in Times Beach, however, as we continued to urge the EPA to speed up its testing, it became clear that fragmented federal responsibility was becoming a substantial impediment to both emergency responses and long-term solutions. In some instances the recommendations and ideas of one particular federal agency did not square with the advice which was being given by other federal agencies. Therefore, I wrote and telephoned the White House to ask the President to immediately establish a federal task force to bring together all appropriate agencies and that a single federal agency and official be designated to take the lead responsibility in Times Beach. The President that same day appointed a federal coordinating group, task force, and named Lee Thomas of the Federal Emergency Management Agency as Chairman. The next day Mr. Thomas and I visited Times Beach and had discussions there and in St. Louis. We continued to work with federal officials to expedite their handling of the problems in all areas of Missouri. It appears that we are beginning to see some significant progress in handling the human problems associated with dioxin. Yesterday as we said the federal officials announced they would buy out the dioxin contaminated property in Times Beach, giving residents there a chance to move out permanently and to begin to rebuild their lives elsewhere.

Meanwhile the residents of the Minker site with whom I visited on Monday are still waiting for an answer to their problems. I strongly urged, and repeat that urging, that federal officials also buy out the homes at the site. We've been promised an answer three weeks from the time of that request which is about two weeks from today.

Unfortunately, as we all know, the Missouri dioxin problems do not stop at Times Beach or the Minker site or even the eastern Missouri sites. Because hazardous waste generators and haulers were unregulated for so many years in Missouri and elsewhere the problem of dioxin and other hazardous chemicals is likely to appear and re-appear throughout Missouri as it will throughout the nation for years to come. Extensive sampling and testing by the U.S. Environmental Protection Agency has confirmed the presence of dioxin at 22 sites in Missouri. I expect that more will be found as the testing continues on the some 80 to 90 sites identified as potential dioxin sites throughout the state. We really are in a situation where we have no precedent for solving this problem. No where else has there been found so much large volume of contaminated soil scattered at various locations under different conditions. That is why the state of Missouri needs your help to solve this complex problem. I ask you today to study very carefully all angles of the problem, keeping in mind the human suffering and the human health hazards that occur, as well as the dangers to the environment, and recommend to me solutions that are practical and technologically sound. To this end I request that you examine and evaluate all known methods, processes and technologies for the destruction and containment of dioxin as it exists as a contaminant in soil and stream sediments at various locations in Missouri. I also ask that you investigate the costs of each of these methods and the length of time required to take remedial action. To the extent possible, I would suggest that you coordinate your study with the ongoing investigations and studies of the U.S. Environmental Protection Agency. Yesterday, Mr. Hedeman in announcing the Superfund activities said that the EPA will be working with the state of Missouri to develop means of controlling, destroying, and containing dioxin. You may want to visit some of the sites where cleanups are underway or the sites where innovative solutions are being tested. Fred Lafser has already pointed out that we have already discovered through the efforts of Syntex some means of destroying dioxin where found in highly concentrated forms and we have some expertise which has already been developed in this area. I am confident that the problem can be solved but it will only be solved by cooperative effort by state, local and federal agencies. At several of the larger sites, obviously, if extensive cleanup is required to protect the health of citizens, we are going to need federal Superfund assistance once again. We also are going to need the assistance of the best knowledge, the best ability, in the private sector. The number of nationally known companies with a reputation for helping solve dioxin problems have written to state government and suggested ideas for dealing with the dioxin problem. I am sure that they would be willing to discuss these ideas with you. We hope that from these sources and other sources which will be available to you, we will be able to come up with some answers. Again, Mr. Lafser and his staff will be able to assist you in your task.

The heart, of course, of the dioxin problem is the human health problem. There has been a great deal of confusion and anxiety regarding the public health dangers associated with dioxin, particularly as it exists as a contaminant in soil and stream sediments in locations throughout Missouri. I'd ask that you examine the data, the analyses provided by the Federal Centers for Disease Control and the Missouri Division of Health. Based on this examination I'd like you to assess for us the public health dangers of dioxin contamination and recommend what other services the state should be providing. Bob Hotchkiss of the Division of Health will be presenting information on these issues this morning and he and his staff will be able to assist you in that part of the assignment.

You should also be aware that I have recommended to the Missouri General Assembly legislation to help combat the dioxin problem. I think some of these actions represent the basic commitments that our state must make. I proposed in January an immediate $1 million in emergency appropriation for immediate relocation of families and cleanup activities. As I mentioned earlier, I have just yesterday urged the General Assembly to appropriate on an emergency basis another $3.5 million for the state match for the buy-out of the Times Beach property and relocation of citizens from that area.

Second, I have proposed that we immediately add five new environmental health officers to the Division of Health on an emergency basis and add two more environmental health officers next year.

Third, we proposed the hiring of a hazardous waste criminal investigator and three environmental landfill specialists to the staff of the Department of Natural Resources so that we may follow up and investigate suspicious circumstances and proceed with prosecution of anyone violating our hazardous waste laws.

Fourth, I've proposed an expansion of the Missouri Superfund, increasing fees on hazardous waste generators, transporters, and waste site operators, to provide us with the mechanisms and the resources to deal with these problems.

As you see the fifth proposal I made to the legislature was the Governor's Task Force of scientific advisors and concerned citizens, the long-term solution, and that is you, ladies and gentlemen. When I said we were going to get a blue ribbon task force, I was generally aware that we had some very unusual and special talents in this state and your presence here today, your willingness to serve and your dedication to these efforts convinces me that we do have the resources in our state that we need to solve the problem.

I'm happy to report that the bills that have been recommended are progressing in the General Assembly and with passage of the legislation we should be able to provide some immediate relief and establish the groundwork for better management of hazardous waste in the future. In the meantime, I turn to you for your help in identifying the permanent comprehensive solutions to the dioxin problem in Missouri. Make no mistake about it, this is a serious and difficult challenge. The nation is watching to see how Missouri will solve the dioxin problem we have here. We must show that we are up to the challenge and prepared to emerge as a national leader in responding to hazardous waste problems. Missouri is not the only state that has hazardous waste problems. They have a particular problem because of the way in which the dioxin was spread across our state and it is a particularly difficult challenge, but the expertise, the knowledge and the information we gain here not only can help the citizens of our state, but I believe can help provide some ideas and leadership for other states in the nation as they too must face their hazardous waste problems.

In the end I trust that we will not only solve the problem, but will restore pride that we have in our state, a pride that has been sagging in some areas in recent months as we have seen on television and heard on the radio and read in the newspapers as the nation has focused on our dioxin problems. When we have found those solutions, Missourians will thank you for the important role that you have played. Today once again, I extend my sincere thanks to you for your agreement to accept this responsibility. I've asked for your time, your dedication, your patience, and your expertise. That combination I am convinced will enable us, in cooperation with the other agencies and the other entities involved, to come up with the solutions that we must have.

x

EXECUTIVE SUMMARY

TASK FORCE RECOMMENDATIONS

This interim report is not limited to Times Beach, but has been expanded to include the Minker/Stout site because this later site is considered to be unstable since movement of contaminated soil is occurring. Following is a summary of the actions that are needed to deal with the problem at these sites. The final report will deal with the problem as it exists statewide.

MINKER/STOUT

- the buyout should be expedited.
- access to the site should be restricted.
- initial stabilization measures should be implemented.
- surface and groundwater sampling should be conducted.
- planning for final remedial action should continue with all deliberate speed.
- more complete health studies should be considered.

TIMES BEACH

- the buyout should be expedited.
- access to the site should be restricted.
- additional sampling of the surface and groundwater should be conducted.
- other than limiting access, no initial remedial actions are recommended unless contaminant migration is found.
- additional soil sampling should be done to determine extent and depth of the concentration.
- more complete health studies should be considered.

AVAILABLE TECHNOLOGY

- test burn soils with varying concentrations of TCDD to demonstrate destruction by incineration and to determine if the ash is non-hazardous.
- continue study and research on solvent extraction and fixation.
- locate site for a storage treatment facility.
- landfilling is to be used only as a last resort.

FURTHER RESEARCH

- the human health effects of dioxin.
- the health of residents of contaminated sites.
- the bioavailability of dioxin in soil.
- stability and transport of dioxin in the environment.

INTRODUCTION

TASK FORCE ACTIVITY

For the past four months, the Dioxin Task Force, appointed by Governor Bond, has conducted an intensive study of the dioxin situation in Missouri. The Task Force has heard testimony and reviewed studies made by experts from throughout the country regarding the environmental and health effects of dioxin. The Task Force also has conducted a study of available technology for disposal of dioxin and has made an assessment of those technologies based on applicability to the specified sites being considered in this report.

As requested by Governor Bond, the recommendations in the interim report deal specifically with the Times Beach site. In addition, the Task Force also related all available information to the Minker/Stout site, another area of high priority. While many recommendations made will be applicable to other sites in Missouri, detailed discussion of those sites will not be made until the final report due in October.

HISTORICAL SUMMARY

In 1969, the North Eastern Pharmaceutical and Chemical Company (NEPACCO) began producing 2,4,5-trichlorophenol (2,4,5-TCP) as an intermediate for hexachlorophene in a Verona, Missouri manufacturing facility leased from the Hoffman-Taff Chemical Company and later Syntex Agribusiness Inc. In the manufacturing process, the product stream was distilled and filtered to remove impurities. Dioxin (2,3,7,8-tetrachlorodibenzo-p-dioxin or TCDD), which was formed in trace quantities during the manufacturing process for the TCP, was removed from the product during filtration and distillation. The filtration and distillation residues thus became contaminated with dioxin. Unfortunately, it was not known at the time the still bottoms contained TCDD.

Missouri's current dioxin dilemma can be traced to May 1971. At this time the problem came to the attention of state and federal officials when a child was hospitalized after playing in a horse arena where numerous horses and other animals had become ill and died. Between 1971 and 1974 officials of the Missouri Divison of Health (DOH) and the federal Centers for Disease Control (CDC) conducted an investigation to determine the cause of these problems. In the investigation, it was discovered that some additional people were ill and that several stables had been sprayed in 1971, as a dust control measure, by Russell Bliss, a waste oil hauler from St. Louis. It was not until July of 1974 that it was determined that a toxic form of dioxin (TCDD) was the causative agent in the oily wastes. Until that time, there was neither reason to suspect that TCDD was involved, nor reason to link these problems with NEPACCO's manufacturing processes in Verona, Missouri a few years earlier.

Meanwhile, the contaminated soil at the horse arenas had been removed by the owners of the arenas and disposed of in various locations. Some of the contaminated soil from the Bubbling Springs arena in Fenton was used as fill material at the Minker and Stout residences in Jefferson County.

On August 2, 1974, the CDC informed the Division of Health that dioxin had been found in the samples collected at the Shenandoah Arena (31.8 to 33 ppm). The CDC then accepted the invitation of Dr. Denny Donnell, state epidemiologist, to participate in a renewed investigation. Dr. Patrick Phillips, of the Division of Health, and Drs. Coleman Carter and Matthew Zack (CDC) began an intensive investigation of the problem.

On August 11, 1974, Dr. Phillips met with Judy Piatt, owner of the Shenandoah Arena, to explain the toxic effects of TCDD and to refer the exposed persons to family physicians for evaluations. On August 13, Phillips learned that the Bubbling Springs arena also had experienced similar horse illnesses. On August 14, 1974, Dr. Phillips interviewed persons connected with Bubbling Springs and obtained information about animal and human illnesses; he also obtained information about sites where the excavated arena soil had been taken (Minker and Stout residences). Phillips interviewed Vern Stout and Valerie Minker on August 14 concerning soil excavated from the Bubbling Springs Ranch arena and learned that the soil was deposited at the Minker residence in March 1973. He informed both persons of probable dioxin contamination and obtained samples of soil for analysis. Test results later showed the soil from the Minker residence to contain 0.74 ppm dioxin and soil from the Stout residence to contain 0.44 ppm dioxin.

The dioxin investigation continued in August and September of 1974 and the toxic wastes were traced to their origin at the Syntex plant in Verona. It was discovered that NEPACCO had bought equipment and leased plant space from Hoffman-Taff (since acquired by Syntex Agribusiness, Inc.) and had used Bliss Waste Oil for disposal of some of its wastes. It also was learned that a tank containing approximately 4,300 gallons of distillation residue wastes from NEPACCO's operation still existed on Syntex plant property at Verona. Tests later showed that TCDD was highly concentrated in the tank's contents at approximately 350 ppm.

For the next few years this tank containing high concentrations of TCDD became the chief concern and focal point of activity on the Missouri dioxin issue. On October 2, 1974, Dr. Clark W. Heath, Jr., director of the Cancer and Birth Defects Division, Bureau of Epidemiology, CDC, wrote a letter to Dr. Denny Donnell, Jr. at the Missouri Division of Health, emphasizing the definite hazard of the wastes at the tank in Verona: "...it is important for the public safety that this material be promptly and safely destroyed." This letter apparently served to focus the attention of state officials on the potential hazard of the wastes in the tank at Verona. Health recommended incineration of wastes from the tank and deep burial of the tank itself.

The final CDC report on the investigation (March 1975) pointed out that the expected half-life* of dioxin was one year and recommended: a) that inaccessible contaminated soil remain undisturbed; b) that soil in residential fills be removed to a landfill; c) that the contents of the storage tank (at Verona) be properly incinerated; d) that the tank be marked and deep buried; and e) that symptomatic persons be followed up. This report was reviewed by the DOH and transmitted to the Missouri Department of Natural Resources (DNR). Because of earlier CDC advice, Missouri officials focused on items c) and d). All symptomatic persons were known to be under medical care.

---

*For a discussion of the term "half-life," see Chapter 7.

The recommendation to remove contaminated soil from residential locations was discussed by DNR and DOH. In light of the knowledge of the expected half-life of dioxin in soil in 1975, levels approaching minimum detectable limits at that time, and the apparent stability of the sites, it appears that a decision was reached not to remove the soil but to resample in an effort to confirm the anticipated degradation rate of dioxin. Dr. Phillips visited the residential sites in September 1976; he confirmed that the soil was not eroding and that vegetation had been established, and he took additional samples which were sent to the CDC lab. (Results were obtained in a phone conversation between Dr. Phillips and Dr. John Liddle, head of the CDC Lab, on November 22, 1982.)

From October 1974 to August 1977, there were many frustrating attempts to find a method for incinerating the wastes from the tank in Verona. In August 1977, Syntex officials reported on a new photolysis process which could detoxify dioxin. Essentially, this process involved breaking down compounds with ultraviolet light. Continued investigation showed this to be a preferable method of destruction, and in September 1979, a final decision was made to use the photolysis method. By August 1980, virtually all the 4,300 gallons of waste had been processed. Nearly 13 pounds of dioxin had been destroyed, reducing the original 343 parts per million dioxin content by more than 99 percent. Syntex had become the first company to successfully and safely degrade large amounts of dioxin by photochemical means.

While the Verona tank problem was being solved,the EPA received an anonymous call alleging that other sites in the southwestern part of the state had received NEPACCO wastes. Follow-up investigation led to the discovery of the Denney Farm site; Baldwin Park in Aurora; the wastewater treatment school in Neosho; the Crider, Erwin, Ray, and Rusha farm sites near Verona, and the potential dioxin contamination of the Spring River.

Beginning in October 1979, attention was focused on the Denney Farm cleanup. The actual cleanup, conducted by Syntex with EPA approval, began in September 1980 and was completed in the summer of 1981.

In January 1981, the wastewater treatment school at Neosho was sampled; certain areas were secured and partially cleaned up by EPA.

In November 1981, Ron Crunkilton of the Missouri Department of Conservation and Dan Harris of EPA collected fish from the Spring River to be tested for dioxin. Preliminary test results received in February 1982 indicated the presence of dioxin in the fish tissue. The Missouri Department of Natural Resources, Division of Health, Department of Conservation, and the EPA conducted public meetings in March 1982 to announce the fish sampling results and issued an advisory to limit consumption of fish from the Spring River.

Also, in early 1982, EPA officials announced their intention to resample the horse arenas and the associated sites where excavated soil had been placed. This sampling took place in May and June 1982; the results were obtained in August and made public on August 18. Subsequent events leading to intensive sampling of numerous sites in eastern Missouri are well known. The recent buyout of the residents of Times Beach has made national headlines out of Missouri's dioxin problem.

Overall, the 11-year-long investigation of dioxin had several phases:

May 1971 - August 1974

Phase I: First appearance of animal and human health problems at horse arenas and investigation determining that dioxin in wastes from the plant at Verona had been the cause.

October 1974 - October 1979

Phase II: Attention focused on the highly contaminated wastes in a tank at the Verona plant and the search for methods to destroy the dioxin in the tank.

October 1979 - April 1982

Phase III: Discovery and investigation of numerous sites in southwest Missouri including Denney Farm site and Spring River.

May 1982 - Present

Phase IV: Resampling of horse arenas and associated sites and investigation of new leads in eastern Missouri. Continued sampling of the Spring River and examination of other potential dioxin sites in southwest Missouri.

In Phase I, the investigation was primarily conducted by the Missouri Division of Health and the Centers for Disease Control.

As a result of state reorganization, the Missouri Department of Natural Resources was established on July 1, 1974. DNR established a hazardous waste project in January 1975 and initiated a major survey of hazardous waste generators in the state in order to determine the type and quantity of waste being generated.

DNR, DOH, and EPA cooperated during the Phase II efforts to find a method of destroying the wastes in the tank at Verona. From January 1975 through June 1977, DNR's primary emphasis, however, was on research and legislative activities leading to the passage of the Missouri Hazardous Waste Management Law in 1977 and later amendments in the Special Session of 1980. From July 1977 to the present, DNR's primary activity in hazardous waste has focused on the development and implementation of regulations to prevent mismanagement of currently generated hazardous wastes. However, DNR also has been increasing its assistance to EPA in the investigation and clean-up of abandoned and uncontrolled hazardous wastes sites, particularly since the 1980 amendments to the state law where authority for clean-up and some funding were provided. In fact, a 1980 report to the Governor prepared to support the legislation indicated there were approximately 100 such sites in Missouri.

In Phase III, the EPA was clearly in the lead in the investigation of newly discovered sites in southwest Missouri, and EPA continues as the lead agency in Phase IV with assistance from state agencies and other federal agencies. The passage of the federal "Superfund" Law in December 1980 greatly augmented the EPA's ability to investigate and cleanup abandoned and uncontrolled hazardous waste sites.

Some controvery has resulted from the March 31, 1975 CDC memo which, among other things, recommended excavation of fills at Minker and Stout sites. Although the records are not definitive and most of the personnel involved are no longer with state government, it is inferable from the facts at hand that state officials chose to concentrate their rather limited staff resources on the Verona tank wastes for several reasons:

1. The very high levels of dioxin in the tank at Verona.
2. The assumption that the TCDD in the tank would never degrade.
3. The advice from CDC and other sources that TCDD in the soil at other sites would degrade relatively quickly with probable half-life between 0.24 and 1.0 years.
4. The lack of a disposal or detoxification method for large volumes of soil.
5. The lack of clearly defined clean-up authority.
6. Lack of clean-up funds and staff for investigation and follow-up.
7. An assumption that the contaminated soil of Minker/Stout was stabilized and would not erode onto neighboring properties. Thus, as far as state and federal officials knew, all relevant parties had been notified when the Minker and Stout families were notified in 1974.
8. Less precise methods of measuring TCDD than are now available.
9. At Verona, a private party (Syntex) existed who was willing to provide money and expertise.

The dioxin issue in Missouri has been clouded with a lot of unknowns and controversies. Consider that the work extended for five years over how to detoxify the 4,300 gallons of concentrated material in the Verona tank that NEPACCO left behind. What to do with the dioxin-laced soils still is a question today and illustrates the frustrations and limited options available.

Overall, history shows the clear need for the statutes which were passed in the late 1970s and early 1980s. Legislators acted first to prevent new problems from the mismanagement of hazardous wastes. Then statutes were enacted to authorize clean up of the old abandoned and uncontrolled waste sites. Passage of the federal "Superfund" law has boosted efforts to clean up these dumps. Through adequate enforcement of the waste management laws now on the books, Missouri can prevent problems like the dioxin dilemma from ever happening again.

DIOXIN INVESTIGATION: CURRENT STATUS

The Missouri dioxin investigation began in the spring of 1971 when various parties began a search for the cause of animal deaths at a horse arena. After the problem was traced to dioxin in the summer of 1974, the investigation was focused on locating the source of the contaminant. The dioxin was quickly traced to the former North Eastern Pharmaceutical and Chemical Co. (NEPACCO) plant at Verona. It further was determined that the Bliss Waste Oil Co. had been subcontracted to dispose of wastes from the site, but instead mixed the wastes with used oil and sprayed several locations for customers as a dust control measure.

During the next several years, the investigation continued in the southwest Missouri area. Government officials concentrated on finding the means to destroy a large tank of highly contaminated material that was left by NEPACCO at its former plant site, a facility since purchased by Syntex Agribusiness Inc. Investigators worked to locate other areas nearby where dioxin-contaminated wastes were reported to be buried.

The pace of the investigation picked up dramatically in the summer of 1982 when results of an Environmental Protection Agency (EPA) testing program indicated that the dioxin molecule is far more persistent in the environment than originally thought. From late summer until mid-January 1983, the Environmental Protection Agency committed substantial resources to locate and document potential dioxin sites in the eastern Missouri area, while still maintaining efforts as necessary in southwest Missouri. Sampling was arranged where indicated. Some assistance was provided by specially assigned personnel from the Department of Natural Resources, who worked under the EPA's direction.

In mid-January, as a result of the increasing number of sites where follow up was required, the Department of Natural Resources' Division of Environmental Quality did assign personnel to coordinate a state investigation and complement the federal effort. The state and federal investigation coordinators agreed that the EPA would continue to handle primarily sites in southwest Missouri while state personnel would assist with the rapidly expanding caseload in eastern Missouri. During the major portion of the recent state and federal investigation, a combined force of about five persons has been following up on leads, interviewing, taking statements, seeking access permission, sketching and photographing sites, and outlining suspect areas in preparation for sampling. As new leads are acquired, the coordinators decide who will assume responsibility for followup.

An original list of 40 suspect sites has grown quickly, with changes occurring so fast that it is difficult to provide an accurate report on the status of the investigation. On a daily basis, sites are confirmed, new leads are acquired, old leads are found groundless, and sometimes one site becomes two.

Investigators are looking for information about sites that may have been sprayed by the Bliss Oil Co. with waste oil or other material at some point after May 1971. Sites sprayed close to this time are of greatest concern. Leads have been provided by arena owners, former Bliss employees, concerned citizens, and the state's "dioxin hotline". Investigators even pickup leads in the course of casual conversations. All leads are taken seriously and scheduled for followup according to their apparent value and risk posed to human health and the environment.

As of May 26, there were 31 sites in the state where dioxin contamination has been confirmed. An additional 102 sites were under investigation. There were 76 sites that have been investigated and determined by EPA to require no further action at this time.

CHAPTER 1

SITE SUMMARIES

This report contains specific information on the Minker/Stout/Romaine Creek and Times Beach sites. Therefore, this chapter presents information for these sites:

Location
Accessibility
Historical Summary
Site and Contaminated Area Description
Geologic and Soils Description
Unique Site Characteristics

Site maps for the Minker, Stout, and Romaine Creek sites were taken from information presented to the Task Force by CH_2M Hill, which is contained in Appendix VII. CH_2M Hill is EPA's feasibility contractor for the Minker/Stout sites.

Location maps and brief summaries of the present 31 confirmed dioxin sites are contained in Appendix VI. As the above information is compiled for all of the confirmed dioxin sites, it will be included in the final report.

Legal Description: Anita Acres, a resubdivision of the north half of Lot 35 of Sunset Acres Subdivision in U.S. Survey No. 1974

By extrapolation of section lines: SE 1/4, NE 1/4, NE 1/4, Section 29, T. 43 N., R. 5 E., 5th P.M.
Maxville Quadrangle
Jefferson County
Latitude: 38° 26' 25"
Longitude: 90° 28' 10"

Address: 4037 West Rock Creek Road
Imperial, Missouri 63052

Accessibility

Access is west approximately 1.3 miles from Missouri Highway 21 on West Rock Creek Road, or northwest approximately 1.3 miles from Missouri Highway 21 on Swaller Road and West Rock Creek Road. West Rock Creek and Swaller Roads are low type bituminous.

History Summary

In June 1971, the Bubbling Springs Ranch horse arena was sprayed with contaminated waste oil. After several incidents of horse illnesses, the arena owner hired a private contractor to remove the soil which was suspected to be causing the problems. In March 1973 about 850 cubic yards was excavated, of which an estimated 260 cubic yards was used for fill at the Minker residence. The Center for Disease Control sampled the site in 1974 and found levels of 2,3,7,8-TCDD ranging from 85 ppb to 740 ppb. This site along with Romaine Creek and the Stout Site is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a feasibility study for the sites.

Site Description (see maps)

The Minker Site lies at the head of Romaine Creek. The Minker house sits near the top of a ridge and the fill area is immediately to the south of the house. The toe of the fill abuts the neighboring yard. The fill was placed in a gully which carries storm drainage to Romaine Creek. Apparently, the fill began to erode almost immediately and most of the fill has now eroded downslope. Hence, the contaminated soil has been widely spread around other residences' yards downslope and into Romaine Creek. EPA sampling during 1982 and 1983 found 2,3,7,8-TCDD levels up to over 300 ppb. Volume of material has been estimated at 5000 to 8000 cubic yards for the Minker and Stout Sites combined.

Several homes are located across West Rock Creek Road from the Minker site. Testing has revealed no TCDD contamination of these properties.

Geologic and Soils Description

The Minker Site is in an upland setting underlain primarily by residual soil derived from weathering of a cherty limestone. A surface veneer of loess is present in limited areas and is usually not a factor in construction projects in the area.

The thickness of the residual soil can range from a few feet upwards in excess of 80 feet. For an average thickness, an assumption of 20 feet is valid for residual soil on the uplands and hillslopes. The clay portion in this soil could be as high as 40% or 50% with most of the remainder of the fine textured portion being made up of silt. The coarser fraction consists of angular to subangular chert fragments and these may range from 10% to as much as 40% of the soil deposit.

The Romaine Creek valley contains material eroded from the residual soil on the hillslopes. Thus, most of the alluvial material is a chert gravel material, with the surface soil being silt rich. The Bubbling Springs horse arena is located on the floodplain of the Romaine Creek.

In conclusion, the contaminated material used as fill at the Minker Site was similar to the residual soil, but having a higher silt content. Due to being spread out by erosion and mixed with residual material, the contaminated soil is primarily a stoney clay.

Unique Site Characteristics

The Minker Site is located in a dramatic topographical area which will complicate any construction or remedial activity. The contaminated material was located in a residential area, in yards and readily accessible to humans. The material is spreading through a large area (Romaine Creek), greatly enlarging the affected area.

Accessibility

Access to the site is northwest approximately 0.7 mile from Missouri Highway 21 on Swaller Road. Swaller Road is low type bituminous.

History Summary

In June 1971, the Bubbling Springs Ranch horse arena was sprayed with contaminated waste oil. After several incidents of horse illnesses, the arena owner hired a private contractor to remove the soil which was suspected to be causing the problems. In March 1973 about 850 cubic yards was excavated, of which the majority was used for fill at the Stout Site. The Center for Disease Control sampled the site in 1974 and found levels of 2,3,7,8-TCDD in the range of 170 ppb to 440 ppb. This site along with Romaine Creek and the Minker Residence Site is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a feasibility study for the sites.

Site Description (see maps)

The Stout Site sits slightly to the east side of a north-south ridge. The fill material was used to make a level lot for two trailer pads. Reportedly, the fill operation was already in progress when the contaminated soil was brought to the site. Contamination was found throughout the fill by EPA sampling at levels from 1.0 ppb to 300 ppb, down to a depth of 20 feet. It is believed that 20 feet is the maximum depth of fill at any point. Volume of material has been estimated at 5,000 to 8,000 cubic yards for the Minker and Stout Sites combined.

Geologic and Soils Description

The Stout Site is in an upland setting underlain primarily by residual soil derived from weathering of a cherty limestone. A surface veneer of loess is present in limited areas and is usually not a factor in construction projects in the area.

The thickness of the residual soil can range from a few feet upwards in excess of 80 feet. For an average thickness, an assumption of 20 feet is valid for residual soil on the uplands and hillslopes. The clay portion in this soil could be as high as 40% or 50% with most of the remainder of the fine textured portion being made up of silt. The coarser fraction consists of angular to subangular chert fragments and these may range from 10% to as much as 40% of the soil deposit.

Surface runoff at the Stout Site would travel in a south-southeasterly direction to enter the main stem of Rock Creek east of Country Club Manor.

The contaminated fill originated from the floodplain of the Romaine Creek Valley, which consists of eroded material from the hillslopes, a clay and chert gravel material with a silt rich surface soil. Thus, the fill would partly consist of a stoney, silty clay material.

Unique Site Characteristics

The Stout Site is located on an extremely steep slope, which will complicate any remedial activity.

The creek flows approximately 5 miles northeasterly to enter the Meramec River at the Jefferson County - St. Louis County boundary.

Accessibility

Romaine Creek Road and West Romaine Creek Road generally parallel the creek, with several crossings. The head of Romaine Creek can be entered from the Minker site. Romaine Creek Road is low type bituminous.

History Summary

The Bubbling Horse Ranch horse arena, sprayed with contaminated waste oil in 1971, was the origin of the contaminated soil in Romaine Creek. When the arena was excavated and the material moved to the Minker Site, the soil began to erode and move into Romaine Creek. Contamination of Romaine Creek has come primarily from the Minker Site, and to a lesser extent, possibly from the Ruth Sullins property and the Bubbling Springs Ranch horse arena. The Romaine Creek site along with the Minker and Stout sites is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a feasibility study for the sites.

Site Description (see map)

The majority of contaminated stream sediment has been found within approximately one mile downstream of the Minker site, in the intermittent portion of the creek. 2,3,7,8-TCDD levels range up to 272 ppb, and generally decrease as the distance from the Minker site increases. Since the contaminated soil was transported into the creek by erosion, it generally does not extend outside of the creek banks. Contamination has been found down to two feet below the surface. Beyond one mile downstream of the Minker site, the 2,3,7,8-TCDD levels are near or less than 1 ppb. Contamination levels of 0.3 ppb and 0.79 ppb found downstream of the Bubbling Springs Ranch could have originated from either the horse arena or the Minker site. Contaminated soil is continuing to be moved during periods of rain. Due to the geology of the area, there is a potential for movement of soil particles in Romaine Creek into the subsurface and groundwater.

Geologic and Soils Description

A highly permeable stoney clay residual soil exists in the upper Romaine Creek watershed, allowing movement of surface water into the subsurface probably including sediment transport 50 to 100 feet or more. The upper part of Romaine Creek, approximately one mile, is considered a losing stream. From the point of water flow, near the northwest corner of Sec. 21, T. 43 N., R. 5 E., a continuous and probably perennial flow would be expected all the way to the Meramec River.

The direction of flow of subsurface water lost into the upper watershed of Romaine Creek including the area of the Minker Residence is anticipated to be northeast. This water and possibly sediment would be expected to emerge as stream flow in the main stem of Romaine Creek or one of its tributaries. It is thought that Bubbling Springs would not receive this localized flow due to bedrock structure and lithologies. It is believed that groundwater recharge to Bubbling Springs is regional. A study currently being conducted by the U.S.G.S. and Missouri Division of Geology and Land Survey will further define the complex hyrology of the Romaine Creek Basin.

It appears that contaminants eroded from the horse arena at Bubbling Springs would not recharge groundwater, but would move into Romaine Creek and stay in the stream channel to its conjunction with the Meramec River.

Unique Site Characteristics

The contaminants in Romaine Creek are currently very mobile. They also pose a threat to water and aquatic life.

Accessibility

The City of Times Beach can be entered by any of three routes. Access is gained by exiting Interstate 44 onto the northern outer road from either east or west of the city. The third access point is from the south from Route W onto local roads.

History Summary

In June 1972, a city ordinance was passed to contract with a waste oil hauler to spray the roads for dust control. Apparently all of the gravel streets were oiled that summer twice and a third time where needed, as recalled by residents. In 1973, the roads were again sprayed by contract. The agreement was to have approximately ten miles of road oiled. Five additional streets had been paved so less oiling was done that year. EPA sampled the roads and right-of-ways in November and December 1982, and found 2,3,7,8-TCDD levels up to 127 ppb. In December 1982, the Meramec River flooded the town. EPA sampling in January 1983 following the flood showed that the contaminated soil remained quite immobile throughout the flooding. On February 22, 1983, the EPA Administrator announced a $33 million pledge from superfund to purchase the Times Beach property under a relocation plan to be developed and implemented by the Federal Emergency Management Agency (FEMA). EPA is planning to have a feasibility study conducted to determine the scope and costs of cleanup alternatives. The city is on the National Priorities List.

Site Description (see maps)

Times Beach is principally bounded by the Meramec River, Interstate 44, and the Burlington Northern Railroad tracks. Being in the 100-year floodplain, the area is relatively flat. The majority of the city's 28 miles of paved and gravel road, shoulders, and ditches are contaminated. Maximum levels of 2,3,7,8-TCDD are shown on the city map. Contamination has been found down to at least two feet below the surface. The City of Eureka, population 3,862 lies immediately to the south and west of Times Beach. None of Eureka's streets were oiled and no contamination has been found within the city. Results of all groundwater sampling in the area have been negative.

Geologic and Soils Description

Times Beach is on an alluvial setting, underlain by alluvial silt to a depth of more than 5 feet. Below the alluvial silts; sand, gravel, and a mixture of silt, sand, and clay would be expected to a depth of from 40 to 50 feet where bedrock is encountered. The water table would be expected to be about at the Meramec River level, between 10 and 20 feet from the surface in most of the area.

The alluvial silt has a relatively low permeability and would be expected to be wet natured in that it does not readily or rapidly drain water. Due to this and the screening effect of the silt, it is not likely that soil particles contaminated with dioxin would move down into the water table.

It can be assumed that the contaminated material consists of road bed material plus native soil where the contamination has eroded into the ditches.

Unique Site Characteristics

The Times Beach site comprises the largest volume of contaminated material of all of the sites. Its location in the floodplain will require extra precautions for any remedial activity.

CHAPTER 2

SUMMARIES OF EXPERTS' PRESENTATIONS

In an effort to become better informed about the current medical and environmental issues surrounding dioxin, the Task Force has heard from a number of experts in the field of dioxin research. Following are summaries of these experts' speeches at the Task Force meetings.

William G. Dunagin, M.D.
Division of Dermatology M173
University of Missouri
Health Science Center

DIOXIN EFFECTS ON HEALTH SUMMARY

Many misleading statements have been made in the press about the health effects of dioxin. Consequently, the fear that many people in the general public have may be out of proportion to the real hazard. For example, the statement that dioxin is 180,000 times as toxic as cyanide has been repeated numerous times in the media. This is certainly not true for any species of mammal. The most sensitive mammal is the guinea pig where the single dose LD_{50} for dioxin is 250 times pure cyanide or 1000 times cyanide salts. These comparisons also assume that one is dealing with pure dioxin. Actually the dioxin in Missouri is in trace quantities expressed as parts per billion.

The single dose LD_{50} for monkeys is 50 micrograms per kilogram. Humans are probably in the same range (Dr. Neal has estimated the level as more than 100. Analogy with Yusho disease indicated the same range). Using this figure of 50 micrograms per kilo for humans, we can see that dioxin is about 10 times as toxic as cyanide.

Dioxin	50 ug/kg
HCN	500 ug/kg
Cyanide salts	2000 ug/kg
Cantharidin	300 ug/kg
Nicotine	600 ug/kg
Colchicine	300 ug/kg
Digitoxin	35 ug/kg

The last four chemicals are on the shelves of every pharmacy in Missouri. The toxicity of dioxin is not totally out of the range of many substances we are used to dealing with. Dermatologist commonly use a preparation that contains seven parts per thousand of cantharidin in order to kill warts.

Another point that is poorly understood by the general public is that dioxin must be absorbed into the body before it can produce any harmful effect. It does not release radation or vapors. Theoretically dioxin can be absorbed through the skin, intestinal tract, or lungs. Dermal absorption may have been important in 1971 when the waste oil containing dioxin was freshly sprayed on horse arenas. The situation today is different. The dioxin is attached to soil particles and is in much lower concentrations. The work of Poiger and Schlatter at the Swiss Federal Institute of Toxicology using soil from Seveso, Italy, suggests that only one percent or less of an applied dose of dioxin in a soil-water mixture is likely to be absorbed through the skin at concentrations below one part per million. This finding is not at all unusual. The percutaneous absorption of most aromatic hydrocarbons varies greatly depending on the vehicle. The amount absorbed topically is insignificant, and others have shown that inhalation of dust containing one part per billion (the level reported by EPA via newspaper accounts as the highest levels in dust from homes in Times Beach is insignificant). So for practical purposes, ingestion of dioxin is the only way that people in Missouri could get toxic effects, today.

The FDA has set levels of 50 parts per trillion of dioxin for ingesting fish on a one time basis or 25 if fish are eaten on several occasions. A 3 1/2 ounce serving of fish would weigh 100 grams. The equivalent amount of soil containing 1 part per billion of dioxin would be 5 grams. It is unlikely that a competent person would ingest more than this without being aware.

The main objective effects of dioxin are chloracne, porphyria cutanea tarda, peripheral nerve damage, and nerve conduction abnormalities (no objective evidence of organic brain damage). Other effects which have occured rarely in humans, probably only at high doses, and are known mainly from animal experiments, are hepatic necrosis, T cell depression and bleeding tendency. Other conditions such as increased triglycerides, have been reported but it is unclear if they are signigicantly increased compared to a suitable control population.

The importance of chloracne is that it seems to be the most sensitive indicator of dioxin exposure. In some examples of low level exposure to dioxin such as Seveso, Italy, and Bolsover, England, it was the only objective finding. In examples of industrial accidents where there was high level exposure, 80-90% of workers who had some of the more serious effects of dioxin also had chloracne. Chloracne was present in 90% of patients with Yusho, a disease caused by chemicals (dibenzofurans) which are very closely related to dioxin.

So for any one individual, chloracne does not have to be present. However, for a large group of people, it is very unlikely that every person would be an exception to the rule. The preliminary reports of the CDC examination of 186 residents of Times Beach were that no cases of chloracne were found. No one from any other site in Missouri today has chloracne to my knowledge. This is very good news, and indicates that the other direct toxicities of dioxin are unlikely.

Another misconception that many people have is that dioxin may cause serious toxicity a long time in the future. Actually, the principle of a long latency period applies only to cancer. Someone whose liver is in good condition today, and who receives no further dioxin, is not going to suddenly come down with massive liver necrosis or chloracne several years from now.

The question of cancer is very complicated. Basically, the doses of dioxin which have caused cancer in laboratory animals are higher than the doses that produce toxicity. This is not the usual concept that the public has of a silent killer. Dioxin is not a carcinogen in the strict sense of the term. It does not alter the structure of DNA. However, it may be a promoter or cocarcinogen. The concept that any amount at all of carcinogen is bad because lower and lower doses may still cause cancer in a lower and lower percentage of people probably does not apply in the same sense for a promoter.

Amoung humans who have had significant exposure to dioxin after industrial accidents (Nitro, West Virginia, Ludwigshafen, Germany, and Czeckoslovakia) there does not appear to be an increased incidence of cancer, overall. Some people have pointed to the date from Nitro as showing increased lymphoma-leukemia. This is not statistically significant. The same data show that cancer of the stomach and colon were less than expected, in fact the statistics would be better for saying that dioxin prevented cancer of the stomach and colon. Actually neither statement is true, but it illustrates how some people can take bits and pieces of data out of context from epidemiologic studies.

The only types of cancer which may be increased above normal levels are a diverse group of rare tumors called soft tissue sarcomas. Even this is not certain, and more work needs to be done.

U.S. Fish and Wildlife Service

DIOXINS AND DIBENZOFURANS IN THE AQUATIC ENVIRONMENT: RESIDUES IN FISH AND ENVIRONMENTAL FATE

Polychlorinated - dibenzo-p-dioxins (PCDDs) and -dibenzofurans (PCDFs) have been measured in fish and other aquatic samples at concentrations from 1 pg/g to in excess of 1 ug/g. In order to measure these compounds at levels of 1 pg/g by GC/MS techniques, they must be separated from interfering substances (PCBs, polychlorinated-hydroxybiphenyls, -phenoxyphenols, and -diphenyl ethers) and concentrated. We employ column extraction and two sequentially linked chromatographic adsorbents to enrich PCDFs and PCDDs from other co-extractives. Fish from a variety of lakes and rivers were analyzed for PCDDs and PCDFs. PCDF residues were more complex thatn PCDD residues, and were dominated by isomers having 2,3,7,8 - chlorine substitution.

PCDF residues were present in samples from all of the Great Lakes and exceeded 100 pg/g in fish from Lakes Ontario, Huron, Michigan, and Saginaw Bay. We measured the ratio of PCB to PCDF concentrations in fish from the Great Lakes to be approximately 100,000 to 1. A composite sample of fish from the Tittabawassee River (Michigan) contained 290 pg/g of PCDFs and 223 pg/g of PCDDs. The PCDF concentrations in fish from Lake Siskiwit (on Isle Royale, Lake Superior) were determined to be 15 pg/g Fish from Lakes Huron and

Ontario, the Tittabawasse River and Saginaw Bay contained the highest concentrations of 2,3,7,8-TCDD. In the Housatonic and Hudson, the composition of PCDD and PCDF residues in sediments differed radically from residues in fish. The residue profiles observed were similar in that the higher congener groups (hepta and octachloro) predominated in contrast to residue profiles in fish where tetra- and pentachloro congeners were dominant.

Contamination from PCDFs is related closely to PCBs. PCBs contain part-per-million concetrations of PCDFs and PCBs can be converted to PCDFs by heating PCBs to temperatures of 300-500 °C in the presence of air or by low temperature burning of materials containing PCBs. TCDD is most frequently associated with chlorophenols and can be produced in high yeilds when 2,4,5-trichlorophenol is heated or burned. Distillation residues or manufacturing wastes from the production of materials made from 2,4,5-trichlorophenol have been involved with most of the TCDD related pollution problems.

Assessment of the impacts and fate of these chemicals in aquatic ecosystems is difficult because only a limited amount of chronic toxcity data is available for aquatic organisms. Exposure of fish fry to low part-per-trillion concentrations has been reported to cause decreased growth and survival. Delayed mortality, 10-15 days after exposure, has been reported.

Data reported from outdoor pond studies provide some insight into the bioavailability and distribution of TCDD in aquatic ecosystems. In one recent study investigating the fate of TCDD in small outdoor pools, a major portion of added TCDD was concentrated in aquatic plants, fish and the hydrosoil-water column interface. Bioconcentration of TCDD by fish in model ecosystem studies was reported to be approximately 6,000 times the water concentration.

No data for TCDF toxicity to aquatic organisms or PCDF bioconcentration factors from water exposure have been reported. However, based on the ratios of PCDFs to PCBs detected in fish, bioconcentration of PCDFs by fish appears to be comparable to PCBs. Fish from contaminated areas could be important as dietary sources of PCDFs and TCDD in humans. The Food and Drug Administration has recommended that fish having residues of TCDD in the range 25-50 parts per trillion not be consumed more frequently than once weekly and fish having more than 50 parts-per-trillion TCDD not be consumed.

The data obtained from analysis of fish and sediments in river systems studies thus far, suggests that TCDD and TCDF are concentrated in fish and other organisms, while the more highly chlorinated Cl_7-, andCl_8-isomers are concentrated in sediment. This altered distribution suggests that TCDD can not be considered to be unavailable to organisms when admixed with soil that is translocated into streams.

ENVIRONMENTAL FATE OF TCDD -- CONCLUSION FROM THREE LONG-TERM FIELD STUDIES

The toxin 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is known to occur as both a contaminant of products made from trichlorophenols and as a by-product from low temperature incineration of wastes containing chlorinated precursors. The magnitude of environmental contamination by the 2,3,7,8-TCDD isomer is currently the subject of intense debate. Although a number of TCDD sources has been identified, environmental monitoring programs for TCDD have generally been unsuccessful in documenting contamination. However, with continued development of sophisticated instrumentation for detecting TCDD in picogram quantities (parts per trillion, ppt) and with renewed interest in monitoring improper disposal of hazardous wastes, additional data on the distribution of TCDD in the environment are being obtained. This paper reviews the environmental data generated from three long-term field studies conducted by the United States Air Force in five distinctly different geographic locations in the United States.

Persistence data on TCDD were obtained from field plots treated in 1972 with sub-surface applications of massive quantities of the herbicides 2,4-dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) in soils of Northwestern Florida, Western Kansas and Northwestern Utah. The fate of TCDD in biological systems was extensively studied in organisms that inhabited a unique 3.0 km^2 military test area in Northwestern Florida that was aerially-sprayed during the perios 1962 to 1970 with 73,000 kg 2,4,5-T containing 2.8 kg TCDD. The movement of TCDD in an aquatic exosystem has been extensively studied in an area adjacent to storage sites (Gulfport, Mississippi, and Johnston Island, Pacific Ocean) where more than 8.4 million L of surplus phenoxy herbicide had been maintained for more than six years. Thus, these studies have provided data on the persistence, movement, bioaccumulation and bioavailability of TCDD in the environment.

Soil Incorporation/Biodegradation Studies: One potential method proposed for the disposal of TCDD-contaminated phenoxy herbicides was subsurface injection or soil incorporation of the herbicide at massive concentrations. The premise for such studies was that high concentrations of the herbicides and TCDD would be degraded to innocuous products by the combined action of soil microorganisms and soil hydrolysis. In order to field test this concept, biodegradation plots were established in three climatically different areas of the United States; Northwest Florida (Elgin Air Force Base), Western Kansas (Garden City), and Northwestern Utah (Air Force Logistics Command Test Range Complex). The Utah site had alkaline soil and a mean annual rainfall of 15 cm, while the Kansas and Florida sites had acidic soils and 40 and 150 cm of annual rainfall, respectively.

Although the method of application was designed to simulate subsurface application of the herbicides and TCDD, the actual concentration of the chemicals varied significantly between locations. The Utah site received concentrations of herbicide exceeding 30,000 ppm (and 140 ppb TCDD) while the

Kansas site had soil concentrations of 2,000 ppm herbicide and 280 ppt TCDD. The TCDD was extracted from soil by using a 1:1 cold solution of hexane and acetone, followed by an acid wash. Confirmation of the compound was done by gas chromatography-mass spectrometry. The results from monitoring the fate of TCDD in these plots indicated that the TCDD rapidly "disappeared" so that less than 15 percent was recovered two years later. Because the plots showed similar patterns in TCDD disappearance, it was suggested that the analytical method was measuring only "free" TCDD and not "total" TCDD. Indeed, examination of archived soil samples using exhaustive extraction techniques revealed that more than 80 percent of the applied TCDD could be recovered. The conclusion of the study was that TCDD underwent a "binding" with soil over time and that a simple extraction technique was insufficient to recover the total TCDD. These data are illustrated in Figure 1.

Fate of TCDD in an Ecosystem: Field studies of TCDD were conducted during 1973-1979 on a unique 3.0 km^2 military test area (Test Area C-52A, Eglin Air Force Base, Florida) that was aerially-sprayed with 73,000 kg of 2,4,5-T during the period 1962-1970. Analysis of archived samples of the formulations indicated that approximately 2.8 kg of TCDD were applied as a contaminant of the herbicide. However, 2.6 kg were applied to a 37 ha test grid (Grid I) from June 1962 through July 1964. Levels of <10 to 1,500 ppt could be found in the top 15 cm of soil 14 years after the last application of herbicide on this site. Nevertheless, analysis of 61 soil samples suggested that less than one percent of the TCDD remained on the test area.

Over the years of observation, approximately 341 species of organisms have been observed and identified as associated with that test area. To date, over 300 biological samples (plant and animals) have been analyzed for TCDD. TCDD residues have been found in a wide spectrum of animals collected from the test area. Approximately one-third (21) of the different species examined for TCDD residue have been positive. In general, the levels of TCDD in the organisms appeared to be close to the mean levels of TCDD found in soils.

Field toxicological investigations were conducted during 1973-1978 on populations of the beachmouse, Peromyscus polionotus. Liver tissue from 36 individual beachmice inhabiting the test site contained 300 to 2,900 ppt TCDD. Although bioconcentration factors (mean liver concentrations divided by mean soil concentrations) ranged from 6 for females to 18 for males a bioavailability mechanism for TCDD in soil may have been operative (see figure 2). Whole body analysis for fetuses from test area females indicated apparent placental transport of TCDD. Histopathological examinations were performed on 255 adult or fetal beachmice from the test area and control area. Mircoscopic examinations were performed on 18 different tissues from each animal. The tissues were first examined on a blind study basis and then re-examined on a control versus test basis which demonstrated that the test and control mice could not be distinguished histopathologically. The mean number of fetuses per observed pregnancy was 3.1 and 3.4 for the test area and control area, respectively. A two-factor (treatment and year) disproportional analysis of covariance of organ weights revealed that liver weights for pregnant beachmice from the test area were significantly heavier (P<.01) than liver weights of pregnant females from the control area, and these differences were consistent over the 5 years of observation. These studies suggested that long-term, low-level exposure to TCDD under field conditions has had minimal effect upon the health and reproduction of the beachmice.

TCDD in Herbicide Storage Sites: During the summer of 1977 the United States Air Force disposed of 8.4 million L of TCDD-contaminated phenoxy herbicide by high temperature incineration at sea. This operation, Project

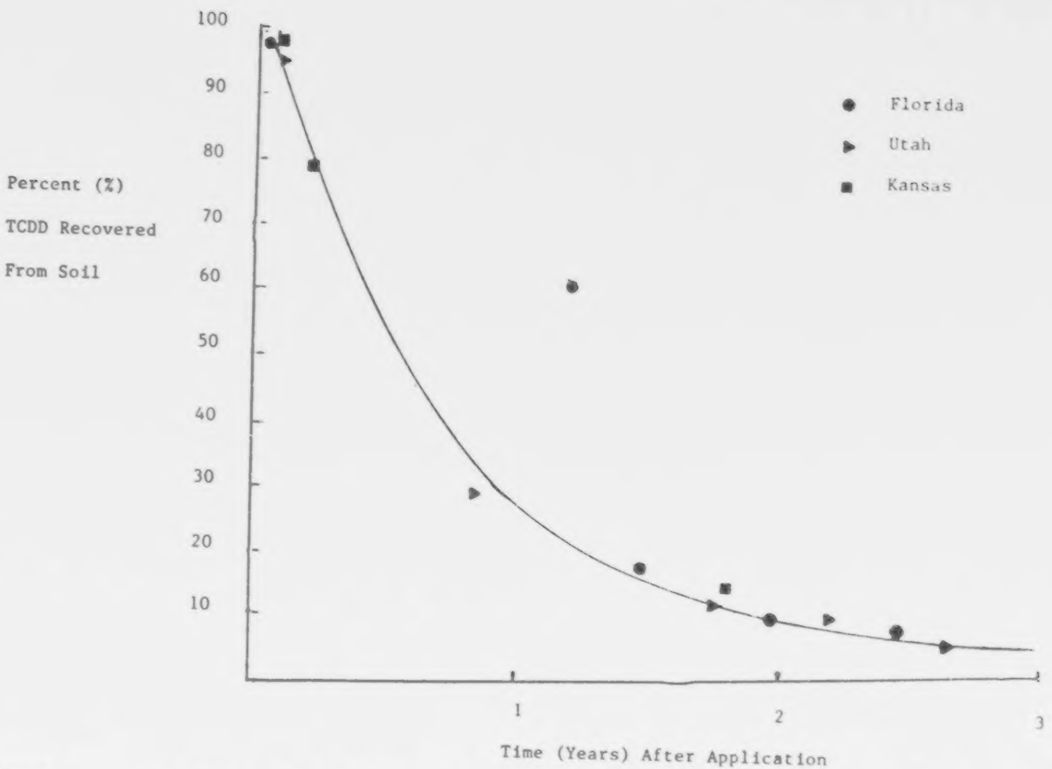

Figure 1. Recovery of 2,3,7,8-TCDD (percent) from three geographically distinct field sites at selected sampling times (years) following soil incorporation of contaminated phenoxy herbicides . [Subsequent re-analysis of soil samples following exhaustive extraction resulted in recovery of more than 80 percent of the original (incorporated) TCDD.]

PACER HO, was accomplished under the very stringent criteria set forth in an United States Environmental Protection Agency (EPA) ocean dumping permit. Among the numerous conditions of this EPA-approved disposal operation was the requirement for the USAF to conduct an extensive storage site reclamation and environmental monitoring program. Details of the proposed site monitoring program were prepared and approved prior to the disposal of the herbicide. The plan recommended that soil samples from the storage areas at both the Naval Construction Battation Center (NCBC), Gulfport, Mississippi and Johnston Island, Pacific Ocean, be collected and analyzed for herbicide and TCDD after the completion of transfer operations. These analyses were to aid in the establishment of a schedule for future monitoring. The site monitoring program would be flexible to requirements generated by construction of any facility on the storage areas and would be concluded upon mutual agreement of all agencies involved. This, the objectives of a site monitoring program were:

1. To determine the magnitude of herbicide and TCDD contamination on the storage areas.

2. To determine the soil persistence of the two phenoxy herbicides (2,4-D and 2,4,5-T) contained in the formulation and the TCDD contaminant.

3. To monitor for any movement of TCDD residue from the sites into adjacent water, sediments and biological organisms.

4. To recommend techniques for managing the storage areas with the ultimate goal of returning the areas to full beneficial unrestricted use.

In July 1977, a preliminary sampling study was initiated. This consisted of assessing the heterogenity of the soils on the sites and the heterogenity of the herbicide concentrations. Twelve sites were selected for sampling at each location; six were in areas of obvious spills and six in areas that showed no spill. Not only were the spills discernible by sight but also by smell. The results from this preliminary study indicated that significant concentrations of herbicides, phenols and TCDD were detected in soils from spill sites. Variations in concentrations and in the ratio of acids to esters suggested that the spills were from different time periods. Accordingly, a more extensive protocol was proposed for future sampling.

The protocol recommended that the sites selected within the two storage areas for monitoring of residue be determined by whether a spill had occured or not occurred at that specific location. The basis for determining a spill was whether a herbicide stain was discernible (heavy, light, absent) and whether a herbicide odor was detectible (strong, mild, absent). Thus, within the storage area numerous locations were found that had a heavy stain and strong odor (presumably representing a recent spill); a light stain and milk odor (presumably representing an older spill); and no stain and no odor (presumably representing an uncontaminated area). Fourteen replication of each treatment were then randomly selected to represent the storage area (thus a total of 42 permanently marked sampling locations at both NCBC and Johnston Island). Twelve of these locations had been tentatively located and marked in July 1977 with the remaining 30 locations and marked in January 1978 with sampling being conducted on these dates, as well in November 1978. In collecting the soil samples, a 8 cm square was marked 15 cm away from the site marker pin. At each sampling time soil was taken from a different "point of the compass" with reference to the marker pin to insure a fresh and undisturbed profile. At the designated site a 8x8x8 cm cube of soil was removed with a ceramic spatula which was rinsed with acetone between uses to prevent carry-over of residue and mircoorganisms. Wherever possible, sediment samples were collected from the drainage areas in a similar manner. Biological samples were collected periodically in these drainage systems at varying distances from the storage sites. Residue studies of areas on the Naval Construction Battalion Center and Johnston Island resulted in the following conclusions:

1. Approximately 1 ha of the 5 ha areas were significantly contaminated with phenoxy herbicides and the associated dioxin (2,3,7,8-TCDD).
2. Levels of 2,4-D and 2,4,5-T herbicides in selected samples from the top 8 cm of soil profile were greater than 100,000 ppm in 1977, but rapidly decreased to one-third that level within 2 years.
3. Levels of TCDD exceeded 0.5 ppm in the soils of many spill sites and have shown trends to decrease over the 3 years of observations.
4. No accurate estimate of TCDD persistence is possible from these studies.
5. Soil penetration of the herbicides was low while soil penetration of TCDD was very low but measurable.
6. Soil sterilization did not occur as a result of herbicide or TCDD contamination, but rather poliferation of certain microflora occurred under high levels of residue.
7. Aquatic organisms found in the drainage system of the storage site at NCBC were significantly contaminated with TCDD (as high as 8 ppb TCDD). The level of TCDD in the organisms and associated sediment decreased rapidly with distance from the site so that samples collected at a distance of 2 km had low ppt levels of TCDD.
8. The principle recommendation for present management of the 5 ha areas at the Naval Construction Battalion Center and Johnston Island is that the areas be left undisturbed permitting the continuation of "natural" degradation of the herbicides and TCDD. Specific recommendations to prevent further movement of contaminated soil from the area included both limiting access to the storage areas and preventing water and wind erosion by stabilizing any potential sites for erosion.

PART II

DIOXIN IN BODY FAT AND HEALTH STATUS: A FEASIBILITY STUDY

Since 1978 there has been mounting concern over human exposure to 2,3,7,8-TCDD. Much of this concern has been expressed by veterans of the Vietnam war who believe that they were exposed to the TCDD-contaminated herbicide, 2,4,5-T, an ingredient of Agent Orange, the major defoliant used by the United States Armed Forces in Vietnam.

During a 5-year period from 1965 to 1970, the U.S. Air Force applied more than 40 million liters of Agent Orange containing more than 92 kg TCDD in South

Vietnam. Some two million American military personnel served 1-year tours during the same period. Many veterans of that era have reported medical problems that they ascribe to exposure to Agent Orange. Their complaints have ranged from tingling in the extremities to rare forms of cancer. Some veterans have fathered children with birth defects and have suggested that the TCDD is the cause. Accordingly, the Veterans Administration (VA) has initiated extensive health studies of veterans exposed by Agent Orange and its dioxin contaminant during the Vietnam Conflict.

Since TCDD is known to accumulate preferentially in the adipose tissue of certain species of laboratory animals, it was suggested, early in the history of the Agent Orange issue, that the analysis of human fat for TCDD might provide a way to determine earlier Agent Orange exposure. A relation between the presence of this substance health problems had also been suggested. Although methods for TCDD analysis have imporved in recent years, no such study had been carried out in humans with known exposure to herbicides containing this toxic contaminant. Consequently the VA embarked on a small feasibility study to test the methodology and to determine whether conclusions might be drawn regarding the significance of the results. The study was carried out in three groups of adult males as follows:

(1) Twenty Vietnam veterans all but one of whom claimed health problems related to Agent Orange exposure and who volunteered for the fat biopsy.

(2) Three U.S. Air Force officers with known heavy and relatively recent exposure in connection with herbicide disposal operations but who did not serve in Vietnam.

(3) Ten veterans with no service in Vietnam and no known exposure to herbicides who were undergoing elective abdominal surgery and who volunteered to serve as controls.

Methods: The prodedure called for the removal of 10-30 grams of subcutaneous adipose tissue from the abdominal wall. This was accomplished surgically under local anesthesia. Precautions were taken before, during and after the procedure to avoid contamination by products, e.g., hexachlorophene, that could contain TCDD. Specimens were collected in glass containers previously rinsed with acetone and dried before use. All tissues were refrigerated during shipment to the assay laboratory. Each of the volunteers had a medical history, physical examination, and routine clinical chemistry. The details of military service in Vietnam from the volunteer's report and his service record were examined to evaluate his potential exposure to military herbicides using the dates, location and nature of his service. From these a rough estimate of the likelihood of exposure to TCDD was made without knowledge of the assay results.

The extraction and assay of all samples for TCDD were conducted at the University of Nebraska, Midwest Center for Mass Spectrometry, Lincoln, Nebraska. Approximately 5 to 10 grams of tissue were used, when available, for each analysis. A known amount, generally 2 ng, of internal standard (either

^{37} C-2,3,7,8-TCDD or ^{13} C-2,3,7,8-TCDD) was added to the adipose tissue. The sample was digested in alcoholic potassium hydroxide followed by extraction with hexane to remove TCDD. The hexane extract was washed with concentrated sulfuric acid, neutralized, dried and concentrated. The final stage of preparation involved the use of three short-column liquid chromatography steps (silica gel, alumina and Florisel). Gas chromatography/high resolution mass spectrometry was employed for quantifation of 2,3,7,8-TCDD and coeluting isomers. Signal profiles were obtained at a mass resolution of 10,000 for m/z 321.8936, the most abundant molecular ion for TCDD, and for the internal standard mass by signal averaging for approximately 100 sec. commencing with the appearance of the co-eluting internal standard 2,3,7,8-TCDD.

Extracts which contained materials giving signals greater than 2.5 times noise at the exact mass of TCDD (i.e. 321.8936 \ 0.0020) over the integration period discussed above were reanalyzed. For the second analysis, signal profiles of m/z 321.8936 and m/z 319.8965 were monitored over the elution period of 2,3,7,8-TCDD (determined by injection of standard solutions). A positive detection was reported if signals were observed above the detection limit (2.5 times noise) and if their intensity ration was 1.0:0.78 + 0.10, which is consistent with the presence of four chlorine atoms in the molecule. Samples meeting all criteria except the correct isotope intensity ration have been considered to contain "not detectable" levels of TCDD. For these samples, it was judged that the presence of TCDD is not disproved by the observation of an incorrect isotope ration at these low concentrations; rather, the presence of TCDD is not confirmed.

Results: Of the twenty veterans who served in Vietnam, seven had no detectible TCDD with the limit of detection at 2 to 6 part per trillion (ppt). Another two had detectible material that could not be validated as TCDD and the results for one was considered equivocal because the measured value was only questionable above the detection limit. Five of the ten remaining Vietnam veterans had TCDD in amounts from 5 ppt to 7 ppt. Three Vietnam veterans had TCDD in the amounts from 9 ppt to 13 ppt. One individual had 63 and 99 ppt (average = 81 ppt) and another had 23 and 35 ppt (average = 29 ppt).

Of the ten control ("unexposed") veternas, four had TCDD indentified in their fat (6,7,7 and 14 ppt). Two other veterans had values low enough to be considered equivocal and in three instances the detected material was not validated as TCDD. The remaining veteran had no detectible TCDD.

One of the three Air Force officers with known exposure had no identified TCDD in his fat. The unidentified substance in his case and the TCDD measured in the other two officers was never more than 3 ppt above the limit of detection.

The clinical data were reviewed, seeking correlations between complaints or diagnoses and the assay results. Within the group of twenty Vietnam veterans, seven of them reported some health problems beginning in or during a tour of duty in Vietnam. No two, however, reported the same symptoms. The remaining thirteen veterans reported no illness in Vietnam although only one reported good health at all times. Among the nineteen veterans with current medical complaints, symptoms and diagnoses varied widely without any common pattern. Five had mental problems ranging from nervousness to schizophrenia and three had experienced difficulties of reporduction, namely, spontaneous abortions by the wives of two and congenital heart disease in the sone of a third.

Four of the seven veterans who reported difficulties while in Vietnam had no TCDD detected. The five veterans with mental problems included three without detectible TCDD and three whose assays results were 5 to 7 ppt. One of three veterans reporting reproductive problems had no detected TCDD, one had doubtful level and one had 7 ppt. Detectible TCDD in the body fat could not be correlated with clinical chemistry findings. Similar results applied to the controls i.e., veterans who did not serve in Vietnam.

The highest values for TCDD in adipose were found in two Vietnam veterans. Both men had military records substantiating duties that involved the use of TCDD-contaminated herbicides in Vietnam. Other individuals, however, who claimed extensive handling of herbicide in base perimeter operations had little or no TCDD in their adipose.

Discussion: TCDD was found in some persons who reported exposure to Agent Orange and in others who were never in Vietnam. On the other hand, some veterans from Vietnam had no detectible TCDD and the same is true of veterans who were never in Vietnam. The low level of TCDD in two Air Force officers and its absence in another is of special interest since their exposure to TCDD is certain and more recent than that of the veterans.

Among the twenty Vietnam veterans there was no uniformity of symptoms, either immediately after exposure, at the time of biopsy, or during the intervening period. No one symptom or group of symptoms was common to veterans with detectible TCDD in their fat. The presence of TCDD did not mean ill health nor did its absence indicate good health. No detailed statistical analysis was attempted of this small pilot series.

The TCDD content in the fat was very small, not exceeding 100 ppt. Since TCDD accumulates in fat more than in other tissue, the average body concentration would be much lower. Even if all tissues contained 100 ppt, however, the concentration would be less than 0.1 mircogram per kilogram of body weight, a value below the demonstrated toxic dose to threaten health.

Conclusions: The present assay for TCDD in fat tissue does not offer a satisfactory routine test for exposure to Agent Orange, providing neither clear evidence of contact with that specific defoliant nor of absence of such contact. Moveover, the technique cannot be used to correlate body levels of TCDD and medical conditions. The assay technique is difficult and not readily available, fat samples must be obtained by surgical biopsy and the source of any TCDD detected is uncertain. The current assay method does provide a research tool under proper conditions and for specific purposes, e.g., for determining the rate of disappearance of TCDD after known exposure.

PART III

A REVIEW OF ON-GOING EPIDEMIOLOGIC RESEARCH IN THE UNITED STATES ON THE PHENOXY HERBICIDES AND CHLORINATED DIOXIN CONTAMINANTS

The use of herbicides to control vegetation has been one of the most persistent controversial subjects arising from the Vietnam Conflict. The United States Air Force applied most of these herbicides in dense jungle areas to uncover and expose hidden enemy staging areas, clear vegetation from the vicinity of military bases and along lines of communication, and to destroy enemy crops. The objectives were to provide defoliated zones that would reduce ambushes and disrupt enemy attacks. The most commonly used "defoliant" was "Agent Orange", a mixture of the two commercial herbicides, 2,4-D and 2,4,5-T, widely employed for many years for brush control in forestry programs throughout the United States and for weed control in agriculture.

During a 5-year period from 1965 to 1970, the U.S. Air Force applied more than 40 million liters of Agent Orange containing approximately 92 kg TCDD (2,3,7,8-TCDD) in South Vietnam. Some two million American military personnel served 1-year tours during the same period. Recently, many veterans of that era have reported medical problems that possibly stem from exposure to Agent Orange during their military assignments. Their complaints have ranged from tingling in the extremities to rare forms of cancer. Some veterans have fathered children with birth defects and have suggested that the TCDD in Agent Orange is the culprit. The basis for resolving the TCDD controversy must in large measure stem from the results of scientific inquiry.

Accordingly, the Veterans Administration (VA) and the Centers for Disease Control have initiated extensive health studies of veterans exposed to Agent Orange and its dioxin contaminant during the Vietnam Conflict. Other federal agencies have initiated studies of populations potentially exposed to chlorophenols and TCDD during manufacturing processes, pesticide applications or as a consequence or improper hazardous waste disposal. Rationale for the more than twenty human studies underway is the need to determine the long-term health consequences of such exposures. Hence, studies are required on mortality, morbidity, reproduction and body burden levels of TCDD. Numerous efforts are underway to clarify the relationship of soft tissue sarcoma and phenoxy herbicides and chlorophenol exposure.

Early Federal Efforts: The United States Environmental Protection Agency, the United States Department of Agriculture and the National Institute for Occupational Safety and Health have all conducted limited studies on the potential associations of phenoxy herbicides and human spontaneous abortions and birth defects. These studies and those conducted in the industrial setting suggest that there is very little epidemiologic data associating TCDD or the phenoxy herbicides with any long-term health effects in humans other than chloracne. However, neither is there strong evidence to validate the absence of such effects. Most studies have not included sufficient numbers of subjects to detect an increased risk of an uncommon condition. Also the period of observation in many studies has been inadequate to detect an illness with long latency period between exposure and illness.

Agent Orange Registry: What has been the response of the Veterans Administration and other governmental agencies to the critical issues raised by Agent Orange? Early action by the VA included the development of a communication process for gathering scientific and medical information which would bear directly on the problem. In addition, early in 1978, the Veterans Administration established the Agent Orange Registry in order to accomplish four objectives:

(1) To identify all Vietnam veterans expressing a concern about the adverse health effects from their exposure to Agent Orange.

(2) To provide a mechanism for Vietnam veterans to voice their concerns to a physician, receive a physical examination and obtain responsible answers to some of their questions.

(3) To serve as a mechanism for follow-up of these individuals if, at a later date, new information develops as a result of the various research efforts underway or being planned.

(4) To obtain, as a by-product, some preliminary information on the current health status of the veternas who have participated in the registry.

The Agent Orange Registry provides us essentially with a listing of names and addresses, together with some background data on a self-reported group of veterans with service in Vietnam. A complete physical examination and a group of baseline laboratory tests are provided to each veteran. The information from this effort is currently being placed into a computer data bank. There are almost 100,000 Vietnam veteran who have been examined by the Veterans Administration. We are in the process of collating the data to determine whether or not there are any significant health trends in these individuals which might suggest areas for further investigation.

TCDD Assay of Human Adipose Tissue: The Veterans Administration, in cooperation with the Environmental Protection Agency (EPA) has initiated an interagency agreement to study levels of 2,3,7,8-TCDD in adipose tissue from a selected group of U.S. males.

The Environmental Protection Agency has been demographically collecting adipose tissue from the U.S. general population (i.e., by region, age, sex and race). This National Adipose Tissue Bank was initiated in 1968 and now contains specimens from over 12,000 individuals. Represented within this bank is available adipose tissue from approximately 500 males born between 1937 and 1952. Many of these individuals would have served in the military during the Vietnam-era and it is reasonable to assume that some actually served in Vietnam during the period of Agent Orange use. A retrospective study of selected chlorinated dioxins and furans may establish data on background levels of 2,3,7,8-TCDD in the U.S. male population as well as whether service in the military and especially in Vietnam has had an effect on the levels of TCDD in adipose tissue.

The study will be conducted in three phases. Phase I will be to obtain the name and social security number for the approximately 500 males noted above. This information will be used to determine military service status. Phase II will be the development of analytic methods for the determination of selected dioxins (especially the 2,3,7,8-TCDD) and furans in human adipose tissue. The method will be subjected to rigorous interlaboratory validation by an independent Analytic Referee, e.g., the Association of Official Analytical Chemists. Phase III will be the analysis of the adipose tissue and the preparation of a final report. Phases I and II should be completed within fiscal year 1983, and the report from Phase III should be available in early 1985.

Vietnam Experience Twin Study: The Vietnam Experience Twin Study was initiated by a group of research staff members at the Veterans Administration Medical Center, St. Louis, Missouri. The study will identify pairs of twin veterans where one twin served in Vietnam during the period of Agent Orange spraying and the other served in an area other than Southeast Asia. Approximately 600 pairs of twins will be examined using a series of psychologic, physiologic and biochemical tests.

The development of a protocol for the study and the establishment of a Twin Registry from which to solicit participants are now underway. The study will focus primarily on the total Vietnam experience rather than any single factor such as Agent Orange. If sufficient numbers of identical twin pairs are identified, there may be an opportunity to draw some conclusions regarding the effects of specific aspects of the Vietnam experience such as combat, herbicide exposure or use of insecticides.

Birth Defects and Military Service in Vietnam Study: In 1981 the Centers for Disease Control (CDC) in Atlanta, Georgia initiated a study designed to determine if Vietnam veterans are at an increased risk of having children with birth defects. Since 1968 CDC has maintained a registry of all babies born with defects in the greater metropolitan Atlanta area. Of the more than 15,000 children in this registry, approximately 7,500 had significant anatomical defects at birth. The investigators will attempt to locate and interview both parents of 5,400 of the children in this group. In addition, the parents of 3,000 control normal babies born during the same time period will be interviewed. Since the major objective of this study will be to determine whether an unusually high proportion of fathers of babies born with defects served in Vietnam, information will be gathered about Vietnam service as well as other factors which may be associated with the occurrence of birth defects. If the study demonstrates that a Vietnam veteran has an increased risk of fathering a child with a defect it may be desirable to attempt to determine if the increase is associated with Agent Orange exposure or with some other factor(s). The study is scheduled to be completed by the end of 1983.

The Air Force Health Study: In 1979 the Air Force initiated the protocol for a comprehensive epidemiologic study of the RANCH HAND personnel, a group of approximately 1,250 men who actually conducted the aerial, fixed-wing herbicide spraying missions in Vietnam from 1962 through 1971. The study is designed around the question, "Have there been, are there now, or will there be in the reasonably foreseeable future, any adverse health effects among RANCH HAND personnel caused by repeated exposure to Herbicide Orange?"

The investigation is composed of three integrated elements -- a mortality study of those individuals who have died since their exposure, a morbidity study to examine the current health status of the study subjects, and a follow-up study to look for delayed effects over the next 20 years. The mortality and morbidity study elements are being conducted simultaneously on the RANCH HAND personnel and a very carefully matched control group by the use of personnel tracking procedures coupled with an extensive review of military medical and personnel records; detailed face-to-face questionnaires to ascertain current and past health events as well as occupational and family data; and comprehensive physical examinations, psychological testing and diagnostic examinations are to be administered periodically during the follow-up phase. Results from the mortality analysis were reported in June 1983 and the results of the initial questionnaire and current health status analysis are to be released in October 1983.

Epidemiologic Study of Ground Troops Exposed to Agent Orange: Public Law 97-151 charged the Veterans Administration to "design a protocol for and conduct an epidemiological study of persons, who while serving in the Armed Forces of the United States during the period of the Vietnam conflict, were exposed to any of the class of chemicals known as "the dioxins" produced during the manufacture of the various phenoxy herbicides (including the herbicide known "Agent Orange") to determine if there may be long-term adverse health effects in such persons from such exposure. Efforts are underway by the Centers for Disease Control (through an interagency agreement with the VA) to complete a protocol and to identify suitable cohorts. This will be a huge research effort which will include interviews and examinations involving several thousands of veterans. A major problem in the design of such a study relates to the fact that there were very few records maintained that would link specific ground troops to herbicide exposure. Another problem encountered is that it is difficult to design data collecting instruments and techniques when the health outcome variables are so ill-defined. However, much design work has been accomplished, and it is hoped that the actual study will get underway early in 1984.

Conclusion: Neither the government nor the scientific community has resolved the numerous controversies (environmental, medical, or political) involving the use of Agent Orange in Vietnam from 1962 to 1970 nor the use of 2,4,5-T within the agricultural setting of the United States, nor the impact of TCDD from improper disposal of toxic wastes. Scientific data on the long-term health effects of exposure to TCDD are at present insufficient to form a concensus. Hence, the scientific community must continue to conduct valid research on this controversial environmental and health-related issue in order to provide a reliable basis for appropriate decision-making. The Veterans Administration stands firmly committed to working closely with other agencies of the Federal Government as well as with the private sector to obtain as many answers as quickly as possible consistent with sound scientific principles in order to resolve this perplexing issue. The resolution of the controversy, however, will be achieved only following the public's acceptance of the outcome of scientific investigations. To that end, scientists must accept the responsibility for not only conducting quality research, but also for translating the results of their efforts to legislators, to the courts, to the media and ultimately to the public at large.

Dr. Robert Neal, President
Chemical Industry Institute of Toxicology

The purpose of my presentation was to review what is known about the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) (Slide 1) to experimental animals and man. In regulating human exposure to TCDD, we are fortunate to have considerable information about the toxicity of this compound to humans. Information on human toxicity is generally not available on other compounds of environmental concern. However, in spite of the existence of a substantial data base, there are aspects of TCDD toxicity about which there is still considerable question. I will attempt to address some remarks to these data gaps.

In my presentation I will confine my remarks to those toxic effects in experimental animals and man which are supported by objective and scientifically sound data. As is generally the case with environmental contamination with toxic compounds, there have been numerous "scientific" opinions for the existence or absence of toxic effects as a result of exposure of experimental animals or man to TCDD which are not consistent with the existing scientific data. I believe it is essential that we differentiate between those concerns or lack or concern for human health or environmental degradation which are based on scientific fact from those based on speculation. With these distinctions in mind groups such as yours will be in a better position to make informed decisions concerning risks or potential risk resulting from human exposure to these compounds.

There have been a number of instances of human poisoning by TCDD. This slide (Slide 2) lists some of the more important ones. First of all there have been a number of accidents in industrial facilities which resulted in exposure of workers to TCDD. Most of these accidents have occurred during the synthesis of 2,4,5-trichlorophenol by alkaline hydrolysis of 2,4,5,6-tetrachlorobenzene. On July 10, 1976, an accident occurred in Seveso, Italy, which resulted in the exposure of a substantial nonindustrial population to TCDD. The importance of this particular accident is that it resulted in the first substantial exposure of women, particularly pregnant women, and children to TCDD under conditions in which unequivocal illness occurred. One minor incident resulted in the poisoning of two, or perhaps three, chemists involved in the synthesis of TCDD. The other major incident listed was the poisoning which occurred when used oil, contaminated with TCDD, was used for dust suppression on horse show rings in Missouri, an incident with which you are very familiar.

The acute toxicity of TCDD is quite variable depending on the animal species examined (Slide 3). The guinea pig is the most sensitive and the hamster the least sensitive of all the animal species that have so far been examined in detail. The acute toxicity in guinea pigs as compared to hamsters differs by approximately 5000-fold depending on the route of administration. It is frequently stated that TCDD is the most toxic chemical known. This is, of course, not true. Botulinum toxin and tetanus toxin are more toxic than TCDD in all species examined. Also, in some species (e.g. the hamster), there are a number of compounds, including some insecticides in commercial use, which are more acutely toxic than TCDD.

What is the acute toxicity of TCDD in humans? In spite of a number of incidents of human poisoning, there is no evidence that a human fatality has occurred solely as a result of exposure to TCDD. However, in all of these incidents of accidental exposure, we have no definitive data on the dose to which humans were exposed. The only reasonably accurate dose-response data for TCDD toxicity in humans comes from studies carried out in Halmesburg Prison in Pennsylvania in the mid-1960's. In these studies, Dr. Albert Klingman of the University of Pennsylvania exposed approximately 60 prisoners to dermal doses of 0.2 to 16 ug of TCDD. These doses were reported to have caused no toxic effects. Subsequently, a similar number of prisoners (approximately 10) were exposed to larger doses, some as high as 7500 ug applied dermally in smaller doses over a period of a few weeks. These doses were reported to cause chloracne. However, no other clinical symptoms were observed in the subjects of these studies. When one considers all of these data, it is reasonable to conclude that humans appear to be one of the less sensitive species to the acute and subacute toxic effects to TCDD.

A number of studies have been performed examining the potential for TCDD to cause reproductive toxicity in experimental animals. This slide (Slide 4) shows the minimum dose of TCDD causing reproductive toxicity in various species and in various studies. The data shown here for monkeys ignores the data generated in studies at the University of Wisconsin. There is considerable controversy surrounding the conduct of these studies. In my opinion, we must await replication of these studies by another laboratory.

It is important to note that the exposure of male mice (but not females) to high levels of TCDD for extended periods of time does not result in a decrease in reproductive capacity in that sex of that species. These data suggest that TCDD may exert its reproductive toxicity primarily in females. It will be important to examine males of other species to verify that this is the case.

There was no evidence of a statistically significant decrease in reporductive efficiency in the populations of women exposed to TCDD in the Seveso incident. I would again like to point to the particular value to toxicology of the data from Seveso. This unfortunate occurrence allows us to assess, although in a limited way, the potential for TCDD to cause reproductive toxicity in human females.

TCDD causes teratogenic effects in mice (Slide 5). The dose required is 1-3 ug/kg/day administered during the 7-15th day gestation. Exposure of pregnant rats to certain doses of TCDD caused kidney anomalies in the offspring. There has been considerable debate whether this effect is a true teratogenic effect or, alternatively, the result of the acute toxicity of TCDD to the fetus. In my opinion, the data more strongly supports the effect being the result of TCDD toxicity. To my knowledge no birth defects have been detected in monkeys born to or aborted from TCDD-treated mothers. Also, there was not a statistically significant increase in birth defects in the children born to or aborted from the pregnant women in Seveso who were exposed to TCDD. It was thought initially that an increase in birth defects may have occurred. However, a more careful examination of the data showed an obvious underreporting of birth defects in that region of Italy prior to the accident involving TCDD. When compared to a broader control base, there was not a statistically significant increase in birth defects observed in the exposed group in Seveso.

TCDD causes cancer in rats and mice (Slide 6). Tumors have been produced in mice whether the exposure is by way of the diet or applied to the shaven skin on the backs of the animals. The fibrosarcomas produced by dermal application of TCDD to mice is a particularly important observation when viewed in light of the suggestion that soft-tissue tumors may be increased in human populations exposed to TCDD.

A number of studies have been carried out looking for an increase in cancer, and in one study, mortality in humans who have been exposed or potentially exposed to TCDD (Slide 7). A study carried out in Sweden among forestry workers suggested a correlation between exposure to chlorophenols and chlorophenoxy acids and an increase in soft-tissue tumors. Subsequent studies in Finland among forestry workers and in New Zealand among agricultural workers (not shown) similarly exposed to chlorophenols and chlorophenoxy acids failed to show a similar correlation between exposure and soft-tissue tumors. Workers exposed to chlorophenols and chlorphenoxy acids are also potentially exposed to various chlorinated dioxins and in some cases to TCDD.

There are a number of confounding factors in the Swedish study which prevent the examination of the existence or absence of a cause-effect relationship between TCDD exposure and soft-tissue tumors in humans. In the first place, the chlorophenols themselves may have been responsible for the increase incidence of cancer. The compound 2,4,6-trichlorophenol is an animal carcinogen. In addition, the forestry workers were also exposed to other commercial chemicals. These chemicals may have been responsible for the increase in soft-tissue tumors. Finally, an increase in soft-tissue tumors was also observed in forestry workers not known to be exposed to preparations containing TCDD. Thus, the correlation between TCDD exposure and an increase in soft-tissue tumors is questionable at this time. However, because of these human data and because dermal exposure of mice to TCDD causes soft-tissue tumors, further study of this issue is clearly warranted. These studies should be carried out in humans which have developed illness as a result of exposure to TCDD (See Slide 2).

An increase in gastrointestinal cancer has been observed in a population of workers poisoned by TCDD in an industrial accident. However, the fact that populations examined was small (about 50 subjects) and an increase in gastrointestinal tumors have not been detected in other TCDD-poisoned populations, raises doubts whether there is a cause-effect relationship between gastrointestinal cancer and TCDD exposure. Finally, a population of U. S. workers (121 subjects) poisoned by TCDD in 1949 have been examined for an increase in mortality and various diseases (including cancer). No increases in mortality or morbidity, including incidence of cancer or death from cancer, was seen in this population.

TCDD can cause a number of toxic effects in experimental animals (Slide 8). In addition to acute lethality, reproductive toxicity and birth defects which have been discussed earlier, TCDD can cause liver damage in some species (rat, mouse), cause a decrease in immunocompetence (mice) and cause an induction of various enzymes in a number of species. The induction of enzymes is not known to have any clinical significance.

TCDD also causes a number of toxic effects in humans. These are shown in Slide 9. Of all the symptoms listed, the development of chlorachne is the most frequent and sensitive response of humans to TCDD exposure. A careful examination of all the available data on human toxicity resulting from exposure to TCDD and the closely related compounds, the chlorinated dibenzofurans, strongly suggest that if chloracne is not present, the individual or individuals being examined have not been exposed to a sufficient dose to TCDD to cause other symptoms of toxicity. Often chloracne is the only symptom of TCDD toxicity seen in exposed humans. However, in the more severely exposed populations, liver damage and neurological effects are also seen. Other symptoms such as weight loss, hyperlipidemia, anorexia, hirsutism and loss of libido are also seen. Another reported manifestation of TCDD toxicity is porphyria curanea tarda. However, because this condition is infrequently seen in humans poisoned by TCDD, it is questionable whether porphyria cutanea tarda is caused by exposure to TCDD.

In summary, the acute toxicity of TCDD varies widely dependent on the species under examination. The current date indicate that man is one of the lest sensitive species to the acute toxic effects of TCDD.

The most common and sensitive symptom of TCDD toxicity in humans is chloracne. In more severely poisoned subjects a number of other toxic effects are seen, the most important of which are liver damage and neurological effects.

TCDD causes cancer in rats when included in the diet and in mice when included in the diet or applied to the shaved backs of this species. The current data do not indicate there has been an increase in cancer in humans exposed to TCDD. However, there is a suggestion that there may be a correlation between soft-tissue tumors in humans and the exposure to TCDD. Whether or not there is a cause-effect relationship between soft-tissue tumors and TCDD exposure will require additional studies.

Jurgen H. Exner
IT Enviroscience

The properties, analysis, and fate of dioxin in soil were described. Data from the literature and from IT Enviroscience's internal research program were extrapolated to potential cleanup approaches. These data show that treatment of dioxin in soil is technically feasible. These treatments, in situ photolysis or chemical treatment and on- or off-site extraction or thermal destruction in incinerators or cement kilns, can be implemented within 2-4 years and are alternatives to long-term process were illustrated by describing the development and large scale implementation of a process that destroyed 14 lbs of dioxin in Nepacco waste contained in a storage tank at Verona, MO. The time from process conceptualization to startup of the chemical destruction plant was 20 months.

Important properties of dioxin that affect selection of treatment processes are low vapor pressure, extremely low solubility in water and organic solvents, and very high soil/water partitiion coefficient. Precise analyses of dioxin in soil are difficult because of non-homogeneity and the possibility of time-dependent adsorption. Therefore, information on the disappearance of dioxin in soil must take into account the validity of the analytical method.

The fate of dioxin in soil is determined by its strong sorption to soil, by vaporization in the ng-fg/m^2 concentrations from the surface of soil, and by photodegradation. Microbial degradation is insignificant, and plant uptake is small.

Field data from Seveso and ITE internal data support rapid photodegradation of dioxin in soil. Important parameters that must be known for an in situ soil treatment process are soil condition and preparation, reaction time and products, and environmental impact. The principle of in situ photodegradation is proven, but accurate economic information requires knowledge of the important process parameters. These parameters must be established in a demonstration project.

Similarly, the principle of extracting dioxin from soil is proven. Valid economics for such a process require understanding of the various methods of contacting solvents with soil; soil condition, consistency, and wettability; extraction efficiency; and solvent recovery and recycle.

Thermal destruction by incinerators or cement kilns requires proper feed preparation, appropriate feed rates and operating conditions, and acceptance of air, water, and ash discharges. The destruction and removal efficiency, which should be greater than 99.99%, depends on dioxin's thermal stability, the residence time, oxygen concentration, and flame configuration within the thermal oxidation system. The rate of thermal desorption of dioxin from soil and the destruction rate of dioxin adsorbed on particulate matter are other important parameters.

HEALTH EFFECTS OF DIOXIN AND ACCEPTABLE LEVELS IN THE ENVIRONMENT

The Centers for Disease Control (CDC) has recommended one part per billion (ppb) as an acceptable level of dioxin (2,3,7,8-TCDD) in soil. Their primary consideration in recommending this level was a concern for children eating soil on a daily basis. CDC's one ppb recommendation is not designed to represent an "all purpose" standard, covering all situations of dioxin contamination. Rather, it is a conservative recommendation, designed for residential property and other areas where children may eat soil on a daily basis.

Levels of dioxin in soil above one ppb should be acceptable for situations where there is less potential for exposure. In fact, CDC has stated that higher levels of dioxin might be acceptable at some other sites such as roads and parking lots where less human contact is likely. In order for dioxin to pose a potential hazard to human health, people must actually be exposed to the dioxin. For example, little hazard to human health is posed by dioxin-contaminated soil buried under a paved road since there would be virtually no opportunity for human exposure.

In humans, no conclusive evidence exists that dioxin has caused cancer, reproductive effects or birth defects. Health effects in humans include: chloracne, liver effects, neuromuscular symptoms, altered porphyrin metabolism and a number of subjective symptoms. Chloracne is considered the hallmark of overexposure to dioxin.

Pure dioxin is extremely toxic in most animal species. Dioxin has produced cancer in laboratory animals (rats and mice) given the compound over the animals' lifetime. In animals, dioxin-related cancer has only been seen at dose levels great enough to cause other serious toxic effects. No effect levels have been established in laboratory animals. These no-effect levels are important because they are used to predict acceptable levels for humans.

Factors which may affect the potential hazard of dioxin in soil include: concentration of dioxin, location (e.g., surface versus buried), accessibility (e.g., restricted area), type of human activity (e.g., play area for children), presence of grass or ground cover, opportunity to accumulate in food chain, proximity to ground water/streams, potential for erosion, and the presence of oils or solvents. In conclusion, standards for sites must be determined on a case-by-case basis since the circumstances and potential for exposure will vary.

CHAPTER 3

OPTIONS FOR REMEDIAL ACTION

Introduction

A number of different options for remedial action have been proposed. This chapter examines in detail the current technology available to stabilize, treat, or dispose of the dioxin contamination in the state.

It must be stressed that certain options may be more suited to some sites than others. Therefore, each option must be compared on a site by site basis. This chapter attempts to review all possible means of remedial action, but does not recommend one option over another. Also, several of the technologies discussed may not be developed enough for immediate, full scale use. And while every attempt was made to include all possible technologies, exclusion of any technology does not necessarily mean that it is not a viable technology.

A great part of the information in this chapter was supplied by CH_2M-Hill, the Environmental Protection Agency's feasibility contractor for the Minker/Stout site. A summary of their remarks before the Task Force is available in Appendix VIII.

Stabilization In Place

Possibly one of the simplest means of dealing with the situation in terms of actual handling of the contaminated soil is to stabilize or secure it in place. This can be accomplished in the following manner.

In order to insure that the contaminated soil is unable to move, and that the dioxin cannot be leached from the soil, some sort of impermeable barrier must be installed. Once the extent of the contaminated area has been determined, a wall of impermeable material is installed around the site perimeter to a depth which penetrates bedrock. This wall or curtain can be made in several different ways. A grout curtain of cement can be installed by drilling a double wall of large diameter holes around the site down to bedrock and filling them with the cement, which will then spread to form the seal. Or a trench can be dug around the site and filled with a slurry of bentonite mixed with soil. The bentonite will then expand to fill any cracks or crevices in the rock and form a seal.

Along with sealing the perimeter, a clay cap at least 4 feet thick must be placed over the site to seal it from above. It is imperative that no groundwater movement occurs through the site.

It is important to note that the success of this method of containing the the contamination is highly dependent on site geology. If the site is unstable geologically, for example with large cracks and fissures in the rock, complete containment of the soil cannot be insured. Also, this method requires a great deal of onsite construction, and once completed, must be monitored indefinitely.

Another, somewhat simpler means of fixation in place is the addition of a fixative directly to the top layer of soil. Either an inorganic fixative or an organic polymer can be used. Examples of inorganic fixatives include cement or flyash, and organics include polyurethane, polyvinyl acetate and urea formaldehyde. The fixative is sprinkled onto the soil surface and tilled in, forming an impermeable cap over the contamination. Disadvantages of this method include the tendency of the fixative to break down over long periods of time.

The great advantage of this method is that contact with the soil itself is minimized in that the soil remains undisturbed. Of course, this method does not remove or destroy the dioxin, but minimizes its availability to the environment.

On Site Storage

Onsite storage essentially involves creating a landfill directly on the site. Some type of structure is constructed either above or below ground to hold the contaminated soil, and prevent exposure to the environment.

With storage below ground, some type of impermeable liner such as clay or a synthetic sheet must be used in order to prevent possible groundwater contamination. Some type of leachate collection system and monitoring wells are also necessary.

Above ground storage can be accomplished with either a concrete structure or an above ground cell with an impermeable clay or synthetic liner. In either case long term monitoring is required.

This method involves a slightly increased risk of exposure in that the soil must be excavated, causing possible dust formation. One advantage is that contaminated material from all the sites can be consolidated on a single site with proper geologic and geographic requirements. Of course, this would involve some highway transport of the wastes, with the attendant increase in risk.

Transport To Secure Landfill

Transport to a secure landfill involves many of the same principles as on site storage. This option includes excavation of the contaminated soil, and removal from the site by truck to a properly permitted hazardous waste landfill.

Since highway transport would be necessary with this option, the vehicles actually transporting the waste would have to comply with the Department of Transportation (DOT) regulations. Up to this point, the only contaminated soil which has been shipped has been for samples. These samples were classified as a Poison B. If bulk shipment of the contaminated soil stays under the same classification, then the soil would have to either be packed into drums or other containers which met DOT specifications for Poison B, or shipped in a tanker which would also have to meet DOT specifications for Poison B.

Once the contaminated soil reaches the landfill, it is treated in much the same manner as in on site storage. Either an above or below ground cell is constructed to hold the material, and all monitoring requirements become the responsibility of the landfill operator. Two landfills exist within a 600 mile radius which are capable of taking the soil.

A major advantage of this option is that with replacement of the excavated soil, the site once again becomes habitable. Some of the disadvantages include the large cost of transport for the distance required, as well as the increased risk of exposure, both from dust formation on site during excavation, and accidental spillage during highway transport. And like on site storage, this method does not destroy dioxin, but minimizes its availability to the atmosphere.

Incineration

One of the most commercially available means of destroying the dioxin in the contaminated soil is by incineration of the soil. Incineration is widely used in the destruction of other hazardous wastes, and can be considered a proven technology.

The basic principle of incineration is to destroy the dioxin molecule by thermal degradation, and several different incineration techniques are available to accomplish this. The first is by direct incineration of the contaminated soil. Although no test burn data on dioxin is available, by comparison with other highly chlorinated organics it is felt that a temperature of 2300°F and a residence time of 2 seconds would be sufficient to destroy the dioxin. Some of the problems with direct incineration of the soil include the thermal inefficiency of heating that large a quantity of soil to 2300°F, and the slagging and other problems which would occur inside the incinerator.

Another incineration technique which would avoid the problems mentioned above is pyrolytic incineration. This is a two-step process in which the contaminated soil is first placed in some type of rotary hearth or other kiln and baked at 1600°F to drive off the organics, including the dioxin. The organics rich gas stream is then fed to an afterburner operating at 2300°F with a 2 second residence time to destroy the dioxin. In this way, the soil itself is not subjected to the higher temperatures.

No matter what basic incineration techniques are used, certain requirements must be met in regards to site preparation, emission controls, and the like. Of course, the soil must be excavated, and some type of size reduction facility will be needed, since the excavated material will probably contain trees, rocks, concrete, road materials, and other materials unsuitable to feed directly into an incinerator. For this size reduction facility, the feed will either have to be dried out or slurried to facilitate handling. The rocks and other large objects will be separated from the soil, screen graded, and crushed in some type of crusher such as a ball mill. If the feed is slurried in, then some type of concentrating step must be performed and the resultant feed put in some type of form suitable for feed into the incinerator, such as pellets. All soil handling should be done by enclosed conveyor, with sprays, splash guards and other suitable dust suppression equipment on all handling equipment.

The actual incineration of the materials can be accomplished by either of the techniques outlined above, in addition to the following emission control requirements. Some type of dust collector such as a bag house is needed to trap particulates from the rotary kiln. The trapped particulate can then be fed back into the rotary kiln. Emissions from the afterburner can be trapped by a venturi scrubber in series with a packed scrubber to trap any organics in the effluent. Process water from the packed tower must then be treated, possibly by reintroduction to the kiln of the solid residues removed.

One possibility not yet mentioned would be to convert an existing area cement kiln to burn the contaminated soil. Several such kilns exist in the eastern part of the state and are not currently in use. Most if not all of the kilns have size reduction equipment already in place. However, the kiln would have to be retrofitted extensively with adequate pollution control devices as outlined above to ensure containment of the dioxin.

Although the technology to incinerate the contaminated soil is currently available, several questions remain to be answered about matters such as ash disposal. Estimates place the amount of ash which will remain at 80% of the original volume of incinerated soil. Since no test burn data is available for dioxin in soil, the residual amount of dioxin in the ash has yet to be determined. And this ash must still be considered a hazardous waste by definition, and would have to be disposed of in a secure landfill. However, if the residual level of contamination in the ash is within acceptable levels, the possibility exists that the ash can be delisted, making disposal much easier. In the case of the cement kiln, the ash may possibly even be used as a component of cement.

The major advantage of incineration is the fact that it is an accepted, proven technology which is already in use on similar compounds. The major disadvantage is the increased risk of exposure, not only from dust caused by excavation of the soil, but from volatilization of the dioxin from the incineration process. Another disadvantage is that the ash is, by definition, still a hazardous waste.

Solvent Extraction

Extraction is a process whereby the dioxin is stripped from the contaminated soil with some type of solvent, which is then treated to remove or destroy the dioxin. The purpose of this method is to get the dioxin into a medium more suitable to work with, and to leave decontaminated, and possibly usable, soil.

A number of different common solvents exist which would be capable of extracting the dioxin from the soil. Examples of such solvents include toluene, hexane, and freon. The solvent that works the best will have to be determined by testing. A less common extraction technique is the use of supercritical fluids. A supercritical fluid is a gas such as carbon dioxide which has been compressed into its liquid phase. Supercritical fluids have shown promise as extracting solvents, and hold one advantage over common solvents. Most of the common solvents which would be suitable as extracting solvents are also highly toxic in and of themselves. And even if the soil is put through a dryer, a certain amount of the solvent will remain with the soil, usually 1-2% by weight. Use of a solvent such as liquid carbon dioxide would not pose a risk to human health. However, the use of a supercritical solvent has some major drawbacks. First, the technology has not yet been developed to a commercial scale. Secondly, working with anything under extreme pressure always increases the risk of explosion or other mishap.

Once a suitable solvent is chosen, the actual extraction process can be examined. First, size reduction equipment will be necessary as described in the section on incineration. The actual extraction will require some type of multi stage contactors. The soil is washed with solvent in the contactor, the solvent is then drained off, and additional fresh solvent is added. This process is repeated until the dioxin in the soil is reduced to an acceptable level. Current estimates place the aproximate number of washes necessary at 10 to 15. When the soil is deemed clean, then it must be dried to remove as much solvent as possible. The contaminated solvent from the various washes is concentrated by means of distillation, or cleaned by some type of adsorption process using activated charcoal or resin. All of the steps described above must be done under vacuum, to insure that no contamination is leaked to the environment.

The last step would be to treat the concentrated solvent in some manner to remove or destroy the dioxin. This can be done in a number of ways. One process which has already been performed is that of U.V. photolysis. Ultraviolet light is shone on the contaminated solvent, ultimately breaking the bonds in the dioxin molecule. Gamma radiation works in a similar manner. Another process is the addition of a chemical reagent to the solvent to dechlorinate the dioxin molecule. Still another option would be to incinerate the contaminated solvent.

Ideally, the major advantage of this method is that the clean soil can be returned to the site, and the contaminated solvent is more easily treated. Also there are a variety of commercially available solvents capable of extracting the dioxin. Unfortunately, there are a number of disadvantages associated with this method. First, no doubt exists that dioxin can be extracted from soils. This is how samples are tested for dioxin. However, no attempt has been made to demonstrate this process on a commercial or even a pilot scale for the treatment of dioxin. Another major drawback is the toxicity of most solvents which are capable of extracting the dioxin. If 1 or 2% by weight of the solvent is left in the soil, chances are the soil would be more toxic than it was prior to removal of the dioxin. Also, liberating the dioxin from the soil with a solvent increases the availability of that dioxin to the environment, increasing the risk of exposure.

Biodegradation

One of the least expensive and most environmentally desirable techniques for breaking down large organic molecules is to subject the molecules to the action of microorganisms. Numerous studies have examined the susceptibility of dioxin to microbial decomposition, mostly in the uncontrolled environment.

Early studies appeared to indicate that dioxin in soil in the environment was disappearing, possibly due to biodegradation. Unfortunately, later studies showed that the disappearance was due to the increasing difficulty of recovering the dioxin which bound more tightly to the soil with time, rather than any microbial action on the dioxin molecule.

More recently, research programs are being conducted to establish organisms which will ultimately degrade dioxin and other chlorinated ring structures directly in the environment. These projects seek either to modify naturally occuring organisms or to apply recent advances in recombinant DNA technology to genetically engineer organisms which are capable of degrading dioxin.

Many of the studies now being done are focusing on the genetic modification of a number of organisms such as anaerobic and aerobic bacteria, yeasts, and algae. Ideally, the organism created would be able to survive in the environment with direct application to the contaminated soil. A more realistic approach may be to engineer an environment more suitable to the organism, and place the contaminated soil within the artificial environment. This approach would allow the control of specific conditions such as temperature, light, oxygen, and pH to insure the survival of the organism.

Following is a sampling of the research projects under way to study the development of organisms capable of degrading dioxin and other chlorinated ring structures.

At the University of Illinois, a bacterial culture capable of degrading 2,4,5-T has been developed by gradually exposing a mixed culture to increasing strengths of the compound. Research is currently underway to develop a variant of the 2,4,5-T bacteria capable of digesting dioxins by use of the same gradual acclimation method. At the University of Helsinki in Finland, researchers are studying the degradation of pentachlorophenol by organisms either anaerobically or aerobically in an effort to understand and apply the mechanisms involved to dioxins and other chlorinated ring structures. And at the University of Cincinnati, studies are being conducted on yeasts to determine if mammalian genes for chemical degradation can be successfully implanted or transferred.

If some type of organism can be discovered which can indeed biodegrade dioxin, the advantages are obvious, both economically and with respect to handling of contaminated materials. However, it must be stressed that at this point, no organism has been discovered, and such a discovery could be many years in the future.

In Place Treatment

The option of in place teatment is an attractive one in that the contaminated soil could be left in place and treated in some manner to destroy the dioxin. There have been a number of different methods proposed to accomplish this. However, most of the proposed methods have not been developed to the extent that they can be considered as viable technology. Some of these methods are described below.

Perhaps the most technologically developed and the most familiar method is that of ultraviolet (uv) degradation, also know as photolysis. Uv degradation was discussed briefly in the extraction section of this chapter in connection with destruction of dioxin in a solvent medium. When used for the decontamination of soils, the method works as follows. Some type of hydrogen donor such as olive or vegetable oil is applied to the surface of the contaminated soil. Then some type of uv light emitting unit is passed over the soil surface, and the dioxin molecules within reach of the uv radiation are destroyed. Then the surface is tilled to expose fresh soil and the procedure is repeated. This method is most suited to areas where the contaminated soil is shallow. However, some uncertainty exists as to the efficiency of this method, because uv radiation cannot penetrate the soil to any depth, and no estimates are available as to the number of passes necessary to appreciably reduce the dioxin level in the soil.

Another possible method of in place treatment which is similar to uv degradation is the use of gamma radiation. Like uv radiation, gamma radiation destroys the chlorine bonds within the molecule. However, gamma radiation is still in the experimental stage, and will need further developement before it can be considered a viable technology.

Chemical treatments have also been researched in regards to in place treatment. Work has been done on the addition of a sodium containing compound such as sodium polyethylene glycol to the soil along with a hydrogen donor. The sodium compound would then act to dechlorinate the dioxin molecule. But once again, this method is still experimental, and needs further work before it can be added to the list of viable alternatives.

Biodegradation can be considered as an in place treatment method, because of the possibility at some point in the future of simply adding the proper organism directly to the soil to decontaminate it. However, as discussed in the previous section on biodegradation, no organism has been isolated or created which is capable of degrading dioxin yet. Current estimates place the length of time to possibly develop such an organism at 5 years or more.

The advantage of in place treatment is obvious in that soil handling and site disturbance are minimal. However, the disadvantage is the lack of a currently available means of treating the contaminated soil in place.

Stabilization In Place Until New Technology Develops

Throughout all the sections in this chapter, certain technologies have been discussed as having merit, but not being available at this time because of a lack of technological or commercial development. The purpose of this last potential remedial action is to provide an opportunity to allow these and other emerging technologies a chance to develop so that they can be considered as viable options in solving Missouri's dioxin problem.

Initially, some type of interim stabilization measures would be implemented, such as capping or sodding to combat erosion, and other measures to insure that no movement of dioxin is occuring. Site access would be restricted to reduce exposure to the contaminant, and a monitoring program would be implemented to see if any movement is occurring. Concurrently, the development of new technologies for the destruction of dioxin would be observed closely and encouraged.

Some of the emerging technologies as mentioned in previous chapters are as follows. Extraction, especially with supercritical solvents, although a proven technology at the bench scale, has yet to be proven commercially for this type of contaminated soil. Biodegradation holds eventual promise as a simple, effective method, but as yet no organism has been discovered that can successfully degrade dioxin. Gamma radiation and chemical treatment with sodium reagents are two possible methods of in situ treatment which require further study.

Still further emerging technologies which were not mentioned in previous sections include lasers, wet air oxidation, and plasma arcs. Treatment with lasers involves the use of a beam of even intensity to destroy the dioxin molecule. Wet air oxidation involves suspending the contaminant in an aqueous solution at elevated temperature and high pressure, and bubbling air or oxygen through the solution, oxidizing the dioxin molecule. The plasma arc utilizes high energy radiation to almost instantly decompose the dioxin into elemental components.

The possibility exists that even more methods of destroying or containing dioxin will be developing in the near future. The option of stabilizing in place and waiting for new technology will provide a wider range of final remedial actions from which to choose.

CHAPTER 4

SUMMARIES OF REMEDIAL ACTION PROPOSALS FROM INTERESTED FIRMS

This chapter contains summaries of remedial action proposals which were presented to the Task Force by various waste disposal and management firms. These summaries were prepared by the firms, and illustrate the commercial stage of development of the various technologies.

Acurex Waste Technology, Inc.

Acurex Waste Technology, Inc. (AWT) is a wholly-owned subsidiary of Acurex Corporation, a diversified technology company of about $50M sales headquartered in Mountain View, California. Acurex activities include environmental and waste-treatment technologies for U.S. EPA and commercial processing of PCB oils for industry and utilities. Dr. Weitzman is a chemical engineer, chief scientist of AWT, and Manager of the Cincinnati laboratory. Dr. Schraub is Manager of Market Development for Acurex Energy and Environmental Division.

AWT is utilizing a proprietary EPA-approved commercial process to treat PCB oils. The PCB molecule is destroyed by chemically combining the chlorine atoms on the PCB molecule with metallic sodium, forming NaCl (table salt) and a small amount of long-chain polymer which is not acutely toxic and is disposable. This novel process also destroys the chemically similar dioxin compound, 2,3,7,8-TCDD, by the same sodium reduction reaction yielding salt and polymers. The destruction process is combined with solvent extraction soil cleaning methods using a special blend of AWT solvents to make up the Acurex Dioxin-Soil Cleanup Process described in this testimony.

The Acurex Dioxin-Soil Portable Cleanup Process consists of these steps:

1) Obtain permits and approvals.
2) Move portable equipment to contaminated site. Equipment includes enclosed soil moving front loader; required number of soil washing modules (Tanks in which soil, rocks, etc, are washed in solvent with agitation); Solvent Reclamation Unit; Clean Solvent Tank; Analytical Laboratory and Records Office for verification and process quality control Sample analysis; Personnel Trailer: special equipment; toilet and shower and clothes dry-cleaning unit; Water truck.
3) Prepare site including security, wetting of soil for dust control, size reduction to fit into about 20 cu yd washing modules.
4) Scoop soils, etc. into washing modules.
5) Fill with clean solvent and agitate at room temperature and pressure for about one-half hour

6) Pump out solvent and refill with clean solvent and repeat washing process until solvent shows soil to be below desired contamination level (such as 1ppb). Note that a unique relationship exists between dioxin left in soil and that extracted into the solvent.
7) The contaminated solvent is then purified for recycle in a low-power standard distillation process.
8). The remaining small volume of solvent containing all dioxins is transferred to a reactor where Acurex reagents and sodium metal dispersion are added to destroy the toxic dioxin by removing chlorine atoms.
9) Dispose of the small volume of dioxin-free sludge (e.g., 100,000 cu yds soil produces less than 1 cu yd of sludge).
10) The safe soil is returned to its original location or placed in suitable location as regulations allow.
11) Equipment is removed and site regreened.

The AWT process has been verified in Missouri by an actual cleanup of a sample of Minker-Stout soil provided by the Department of Natural Resources at the University of Missouri Environmental Trace Substance Center in Columbia during February, March and April of 1983. Some analytical problems (interference peaks in the gas chromatograph analysis) were encountered but overcome by the combined efforts of DNR, U. of Missouri and Acurex staff.

The Acurex Dioxin-Soil Portable Cleanup Process is estimated to cost about $250 per cubic yard of soil for a 10,000 yard size cleanup job of which $100/yd is the variable cost.

The R&D phase and the initial laboratory demonstration phase are now complete. We believe that AWT process to be a viable technology and a serious candidate for large-scale dioxin soil cleanup and destruction. The next step is a pilot-scale (e.g., one full size washing module) field demonstration affecting a small dioxin site cleanup. Such a program was suggested at a cost of between one-half and one million dollars and a one-year schedule.

In summary, AWT has a novel process to destroy dioxins in soil which is already demonstrated to work on the Minker-Stout soil. The Acurex Dioxin Soil Portable Cleanup Process has these benefits: cleans dioxins, PCB's and other halogenated organics from soil down to a specified level; destoys the dioxin molecules; is safe using non-flammable, non-toxic solvents; is controllable and verifiable, creates no secondary pollutants or migration of existing pollutants; and is already demonstrated in Missouri.

We believe this techology merits thoughtful consideration in the solution to the Missouri dioxin soil problem.

Chemical Waste Management

Late in 1982, then the dioxin problem in Missouri began to receive a great deal of attention, Chemical Waste Management, by virtue of its extensive experience in hazardous waste site mitigation, began a search for a solution to the problem.

In the selection of a project approach, nine key factors were considered:

1. Public health and safety during project implementation and final completion.
2. Technical feasibility.

3. Operational soundness.
4. Provision of an environmentally sound and defensible solution.
5. Compliance with regulations.
6. Timing.
7. Cost.
8. Public reaction/opinion/perception (in Missouri).
9. Public reaction/opinion/perception (in other states).

Using these key factors, four potential treatment/disposal options were evaluated, breaking each option into positive and negative factors. After evaluating incineration, secure burial, treatment, and site capping/encapsulation, the following conclusions were reached:

1. Due to the large volume of soil, destruction of dioxin with the soil is cost prohibitive;
2. Since dioxin is the major concern, it should be extracted from the soil in order to reduce volume;
3. Dioxin which is excavated/extracted should be destroyed through incineration;
4. Again, due to the volume of "low level" dioxin-contaminated soil, removal and destruction of dioxin with the soil is cost prohibitive;
5. Site capping/encapsulation should be an alternative solution for select "low level" sites;
6. Because of public reaction/sensitivity by other states to receiving dioxin, as much of the dioxin processing/disposal should be done within the State of Missouri as is possible.

In light of these conclusions, Chemical Waste Management recommends the following primary operations:

1. Excavation of highly contaminated soils and replacement with clean fill;
2. Site capping/encapsulation of "low level" dioxin contaminated sites;
3. Extraction of the dioxin from the soil;
4. Disposal of treated soil in a secure landfill;
5. Destruction of the dioxin in the extract medium via the ultraviolet light process;
6. Incineration of the treated extract medium at sea via one of CWM's ocean incineration vessels.

Based upon the information at hand, Chemical Waste Management estimates time required for completion of the project to be from 14 to 24 months, with costs ranging from $22 million to $65 million, depending upon the establishment of acceptable levels of contamination and the number of sites to be cleaned up.

Chemical Waste Management, in conjunction with Battelle Memorial Laboratories, is currently conducting tests on dioxin contaminated soils. When those tests are complete, the preliminary estimates will be further refined.

In terms of the key factors and the evaluation of potential treatment/disposal options, Chemical Waste Management believes that the primary operations outlined above represent the most environmentally sound and cost-effective solution to the dioxin problem in Missouri.

Critical Fluid Systems Inc.

Critical Fluid Systems, Inc., is a chemical process engineering company that designs and sells a variety of proprietary extraction systems based on critical fluid technology. These new extraction techniques fill a range of processing needs in such industries as pharmaceuticals, food and organic chemicals as well as waste treatment. Critical Fluid Systems, Inc., was formed in January 1980 as a subsidiary of Arthur D. Little, Inc., to commercialize industrial applications of the patented technology. The company is headed by Dr. Richard P. de Filippi, who initiated the technical development work in the international consulting firm's laboratories in 1976; Critical Fluid Systems' offices, laboratories and pilot plant are located in Cambridge, Massachusetts.

Critical Fluid System's verstile technology, is based on the use of condensed gases as extracting solvents, which provide more economical, and more efficient, alternatives to distillatin, conventional solvent extraction and various incineration and landfill techniques for the management of hazardous wastes. For example, one critical fluid process can be used to clean up soils contaminated with toxic materials.

The State of Missouri faces a massive cleanup of dioxin contamination in Times Beach and other communities. The removal of dioxin presents some very special economic and technical problems - problems which widely used, conventional solvent technologies for waste treatment have not yet succeeded in solving.

The use of critical fluid extraction to strip soils of contaminated material is technically feasible and, in the view of Critical Fluid Systems' engineers, worth trying at Times Beach. Although never applied specifically to dioxin, the technology has been successful in extracting other chemicals and materials from soils. For example, in laboratory tests, Critical Fluid Systems' engineers have separated lubricating oils from steel-making mill scale, diesel oil from cuttings produced in oil well drilling operations, and vegetable oil from spent bleaching clays in food processing. These test results provide reason to believe that the technology might succeed in removing dioxin from soil substrates.

Company officials emphasize, however, that success in such special problems can never be assumed. They propose, therefore, that the State of Missouri underwrite a small scale preliminary test of the efficacy of critical fluids in Times Beach dioxin/soil samples. The company would work with an approved EPA contractor to process samples using a variety of condensed gas solvents and operating conditions. At the completion of the test program, which, if appropriate, would include preliminary estimates of capital and operating costs for a commercial scale facility, a recommendation would be made on the feasibility of proceeding with subsequent phases leading to construction of a full-scale processing plant to be operated by a major waste management company.

The special properties of critical fluids in separating substances have been known to chemists for many years but have only recently been applied on a commercial scale. The first commercial applications have been to extract hops for brewing and to decaffeinate coffee.

Critical Fluid Systems' patented extraction method utilizes fluids that are liquefied gases. At a certain combination of temperature and pressure, these gases reach what is called their critical point. At this point the gases are neither liquid nor vapor but have many of the solvent properties of both. These properties make extraction more rapid and efficient than processes using distillation and coventional solvent extraction methods.

Critical Fluid Systems is currently working under contract to a number of government agencies on critical fluid development projects that include applications for treating and decontaminating solid wastes, extracting chemicals, including pesticides, from waste water, and regenerating activated carbon and other adsorbents used in manufacturing.

SCA Chemical Services, Inc.

Decontamination or destruction of the dioxin contaminant in large volumes of material (soil, construction debris, and furniture) presents challenges that exceed current proven state-of-the-art destruction or decontamination techology. One method has been burial of the contaminated material in specially constructed cells. When material contaminated with dioxin is buried, the problem has been placed in storage for others to solve at a later date. Decontamination or destruction of the contaminant dioxin found in small quantities in the large volumes of contaminated soil located at the various sites in Missouri poses a technical and waste management challenge of unprecedented magnitude. SCA Chemical Services, Inc., one of the nations's largest hazardous waste treatment and disposal companies is pleased to accept that challenge.

SCA recognizes that there is no proven contamination or disposal technology capable of decontaminating large volumes of solid contaminated with dioxin levels ranging from 1 to over 300 parts per billion. The actual level of decontamination to be reached in order to certify the soil free of dioxin and suitable for unrestricted use has yet to be established. Therefore, SCA assumes that any acceptable decontamination or destruction process must achieve average levels of dioxin significantly less than 1 part per billion in the resulting decontaminated material. To date, no large-scale treatment or disposal process has been operated with documented destruction of a contaminant, especially one as persistent as dioxin, bonded to soil particles or soaked into concrete block, to achieve concentration levels significantly below 1 part per billion. It is tempting to make assumptions that certain technologies will work; however, a much more scientific approach is required in order to select candidate treatment processes. Initial evaluation by SCA for the preparation of this proposal has determined that there is no proven off-the-shelf system available to meet the dioxin decontamination challenge.

The existing situation is further clouded by the fact that dioxin is currently regulated by the Toxic Substance Control Act (TSCA). EPA proposed new regulations that would transfer dioxin from the TSCA regulation to the Resource Conservation and Recovery Act (RCRA) regulation in accordance with 40 CFR 261-265 and 40 CFR 122. After the public comment phase, the regulations will be revised to reflect public comment and concern. At this time, it is difficult to project whether or not dioxin will be transferred from TSCA to RCRA and, if so, what the content of the final regulations will be. In either case, any material contaminated with dioxin will be subjected to specific controls and regulations. Such specific controls and regulations will limit the number of commercially available treatment facilities permitted to receive or treat dioxin contaminated material. In addition, the public reaction in host states to the import of large amounts of dioxin contaminated soils must be considered. Because of these many unknowns, it is prudent to assume that the disposal or decontamination of dioxin contaminated materials must be accomplished within the boundaries of Missouri.

In order to meet the technical challenges associated with the successful design, construction and operation of a dioxin contaminated materials decontamination and disposal facility, a multi-disciplined technical and management team will be required. Such a team must have access to the most advanced technologies available in the world, be highly skilled in the evaluation and testing of all types of candidate decontamination systems, be capable of translating conceptual design to a final facility design and supervising the construction of such a facility, be knowledgeable of all regulations and hazardous waste management techniques, and be capable of operating the facility in the most effective and safe manner possible. SCA has assembled such a team to respond to the challenge issued by the Governor's task force on dioxin and the Missouri Department of Natural Resources. The team is comprised of the best technical engineering, construction management, and operational personnel available in the United States today. With the exception of Battelle Columbus Laboratories, all team members are residents of Missouri.

The initial phase of the project will be screening and evaluation of candidate technologies. Laboratory tests may be required in order to complete evaluation of these technologies. The selected technology must be verified by a full-scale pilot operation prior to commitment of the process to final engineering design. Battelle Columbus Laboratories has been selected as the technology team member because of their unequaled capability and knowledge of all types of chemical processes, their extensive laboratories and small-scale test facilities, their current experience as a leading laboratory performing analysis of dioxin contaminated soil samples from Missouri, and their extensive experience in evaluating similar types of problems for the United States Environmental Protection Agency and the United States Army. Battelle has recently completed a $250,000 technology evaluation study for the U.S. Army to determine the best means of decontaminating large volumes of toxic materials, chemical agents and chemical munitions. Battelle Laboratories, Inc. is a not-for-profit research and development center with revenues exceeding $400,000,000, much of which were directly applicable to waste management. Battelle is a recognized authority on various types of hazardous waste treatment technologies including incineration, solvent extraction, and genetic engineering. Battelle has current experience in all types of processes suitable for consideration for decontamination of dioxin contaminated materials.

Once the decontamination technology has been thoroughly tested and confirmed it must be translated into a facility design suitable for construction. SCA has chosen the Fru-Con Corporation, with World Headquarters in Ballwin, Missouri. Fru-Con is a full service engineering and construction corporation. Two elements of Fru-Con are participating in this project. Fruco Engineers, Inc. is an experienced engineering firm with an international reputation for excellence specializing in the design and construction management of cement plants, chemical plants, refineries, industrial facilities, and major buildings. Fruin-Colnon Corporation Contracting Company will provide construction of the facilities. Fruin-Colnon are experienced constructors who have constructed numerous cement plants, chemical plants, refineries, wastewater treatment facilities, and major buildings throughout the State of Missouri, the United States, and internationally. SCA Chemical Services, Inc., a wholly-owned subsidiary of SCA Services, Inc. is one of the major solid waste and hazardous waste corporations in the United States. SCA Chemical Services, Inc. (SCA) operates six major hazardous waste treatment and disposal facilities throughout the United States, has major research and development laboratories in Buffalo, New York. One of its six operational facilities owns and operates the largest commercial hazardous waste incinerator in the United States located near Chicago, Illinois. SCA is an experienced hazardous waste management company that has placed its emphasis on high technology treatment of hazardous waste. It is SCA's established philosophy that land burial of hazardous waste is the option of last resort and should only be utilized when no other treatment technologies are available. The SCA project will be directed by Mr. James L. Boyland who is currently Director of Business Development located in St. Louis, Missouri. Mr. Boyland served on the Department of Natural Resources ad hoc committee for hazardous waste and is experienced in hazardous waste regulations and hazardous waste management.

The SCA team does not approach the decontamination of dioxin contaminated material with preconceived ideas or proprietary processes. Rather, it will evaluate the situation, all relevant data, and proceed to identify those solutions that appear practical. It is the purpose of this proposal to provide the State of Missouri with the option to go forward with the technology development, design, construction, and operation of a dioxin decontamination facility. Such a facility may prove to be necessary in the event that other licensed hazardous waste disposal or treatment facilities are unable or unwilling to accept the large volumes of dioxin contaminated soils from Missouri. The high cost of transportation of such large volumes of soil to remote facilities is also a major cost consideration. With a proper plan and qualified contractors, the State of Missouri should be able to request and obtain federal funding for the required technology development, design, construction, and operation of a dioxin contaminated facility located within the State of Missouri. The SCA team stands ready to support the State of Missouri in any way possible in order to achieve such a goal.

Rollins Environmental Services, Inc.

Presently, there exists many options for the destruction or disposal of extremely hazardous waste (i.e., PCB's, radioactive waste, organic pesticides and herbicides) and many of the same methodologies are being suggested for the treatment of dioxin waste. Unfortunately, there is very little data, if any, on the effectiveness of these methods to treat dioxin materials. Compounding this problem is the large volume of dioxin waste material requiring treatment in Missouri. Most of the present options are not applicable to a large scale problem such as this, except at extreme costs.

Rollins Environmental Services (TX) Inc. (RES) presents the following discussion of thermal oxidative destruction, solvent extraction and land disposal methods that may have application to the dioxin problem. Suitability of these options is based on economics, scale of operation and practicality of the solution. To minimize the number of cost options, we assumed the establishment of a local treatment facility in the St. Louis area for on-site versus off-site (out-of-state transportation cost) treatment.

Thermal Destruction

Our best estimate of the cost of off-site incineration is $234,806,000.00. This number includes excavation, transportation and incineration at a permitted facility. The project time for off-site incineration is estimated to be 3-5 years. On-site incineration with a portable or temporary unit would also be a time intensive option costing $411,100,000.00 and taking greater than 20 years to complete the incineration of the waste with available technology.

Equally important is the disposal of large quantities of incineration ash generated by this disposal method. If the waste ash can not be delisted, it will require disposal in a Class I landfill, further increasing the total cost of incineration.

Solvent Extraction/Oxidative Destruction

Both solvent extracton and oxidative destruction methodologies, in theory, are viable options for dioxin removal, but the technological-operating problems to apply these methods would be more cost intensive than incineration.

Land Disposal

Land disposal, as an option for the treatment of extremely hazardous waste is quickly becoming obsolete with respect to other treatment technologies. The issue of securing a hazardous waste below grade is being questioned because of the uncertainties of these facilities.

Rollins Environmental Services (TX) Inc. is engineering (is developing) an above ground closure method that addresses the problems associated with the below grade secure landfill. The advantages of our above ground closure method include:

1. Only one handling is required and this is bulk handling. Therefore, dissemination of the material is greatly reduced.
2. If the contaminated soil is land-disposed in a secure, aboveground, well monitored site, the problem of future contamination is eliminated.
3. The time of removal from public area is rapid.
4. Transport costs and hazards of shipment to a centrally located above ground closure are minimized.

5. Dioxin has an extremely low solubility in water. If protected from rainfall and surface runoff, it is non-migratory.
6. There is a half life to dioxin - but this may depend on matrix and environmental conditions.
7. There are reports of 5 strains of bacteria which are active with dioxin - leading to the interesting possibility that the material may be inoculated to speed dioxin destruction.
8. Naturally, costs would be appreciably lower for local land disposal.

Above ground land disposal is an environmentally sound method for this waste because it is protected from rainfall and runoff contamination. The construction of a central storage for all dioxin waste, if monitored by a responsible organization, will give the best remedy for the available funds until a final solution is found.

Cost Estimates for Above Ground Closure

Past project experience would indicate that the entire contamination (as presently known) in the St. Louis area could be contained in a twenty acre site with a twenty foot high above ground closure. Assuming the same transportation and excavation costs outlined earlier and assuming one centrally located site, the estimated costs are as follows:

Excavation	$12,500,000
Transportation	$ 1,600,000
Construction & Waste Placement	$12,500,000
Total Estimated Cost	$26,600,000

Project time could be very flexible. Individual sites could be excavated at the rate of 1000 to 3000 cubic yards per day. The limiting factor would be at the central closure site. However, this site could be designed to handle 5,000-10,000 cubic yards per day. Based on these handling rates, the project culd be executed in 2-3 months at an estimated cost of approximately $50.00 per cubic yard.

The above ground closure approach obviously satisfies the economic, scale of operation and practical considerations.

Summary

In summary, Rollins Environmental Services (TX) Inc. recommends a land disposal/above ground closure methodology for the dioxin problem in Missouri because:

1. It places the dioxin contamination in a secure position, out of the public domain, within the fastest time frame,

2. present technologies of incineration and solvent extraction may create additional hazards due to multiple handling of the waste material, and

3. an above ground closure facility will insure secure storage of the dioxin waste until such time as a viable treatment method is developed (i.e., chemical or biological degradation).

IT Enviroscience

It Enviroscience (ITE), a division of It Corporation, has been engaged in dioxin decontamination and analysis activities for the last six years. We are familiar with the literature and much of the on-going research in this field. Also, we have expended considerable internal resources in testing destruction techniques in the laboratory and in evaluating various engineering concepts. We believe that there are several technically feasible dioxin treatment methods that have been proved in principle. These methods are thermal destruction, soil extraction and treatment of the extract, in-situ soil treatment, and soil stabilization.

ITE does not recommend any single treatment technology at this time but proposes technical evaluation for comparison purposes. After the final decision, IT is prepared to design and/or operate the disposal process.

Selection of the appropriate treatment technique for Missouri soil should await technical demonstration of the method. In this manner, important scientific, engineering, and economic parameters can be defined. In the proof-of-principle stage of any process, differences in engineering assumptions commonly lead to variations in cost estimates. Only after technology demonstrations in engineering scale equipment can appropriate comparisons be carried out.

Thermal oxidation evaluation requires two parts, an engineering study to define the ITE-cement kiln process, described below, and a demonstration of thermal destruction efficiency using the U.S. EPA mobile incinerator. The engineering study is estimated at $50,000 in 3 months, the demonstration burn at $1,000,000 within one year.

Technical demonstration of solvent extraction can be carried out for about $250,000 in 9 months, demonstration of in situ treatment can be provided for $100,000 to 250,000 in 9 months, and demonstration of soil stabilization for about $200,000 in 9 months.

ITE has facilities suitable for handling large quantities of dioxin and the personnel knowledgeable in dioxin chemistry, engineering, waste incineration, and plant operation. We propose an unbiased technology evaluation of processes that the Governor's Task Force wishes to pursue by weighing toxicological, technical, economic, and social factors.

Thermal Oxidation

At present, thermal oxidation of dioxin-contaminated soil has the highest probability of any process for achieving complete destruction of dioxin. Technical parameters that must be defined are the destruction and removal efficiency (DRE) for dioxin, which is a function of dioxin's stability and rate of volatilization from soil. Other important parameters are soil variability, handling, and feed rate to a rotary kiln. These and other questions must be addressed before the public will accept thermal destruction as an appropriate technology.

Suitable demonstration of this technique may be carried out by using the U.S. EPA's mobile incinerator.

Economics of thermal destruction depend on the equipment used for that purpose. A new rotary kiln incinerator, shown schematically in Fig. 1, can be designed and built within 2 to 4 years at a capital cost of about $7-20,000,000.

A potentially more economical solution involves modification of an existing cement kiln. Normal considerations for using cement kilns for hazardous waste destruction require adding a secondary combustion chamber, as in Fig. 1, and air pollution equipment to the cement kiln. Use of a secondary combustion chamber adds capital and large fuel costs to normal costs of operating a cement kiln. Fuel costs for such a facility range from $50-200/ton of soil.

Cement kilns provide large residence times for solids at temperatures equivalent to those found in rotary kilns of hazardous waste incinerators. If dioxin-contaminated soil is introduced at the burner end of the cement kiln, there is adequate time to obtain burnout of dioxin at 2,000°F before the ash is dripped into the clinker cooler. The gases will be exposed to 2200°F for more than 2.2 seconds, normal requirements for destruction of PCB, a compound of similar stability as dioxin. This concept is illustrated in Fig. 2. The recycle of decontaminated soil is for purposes of heat and material balance and for gas cooling and cleaning.

If this ITE concept can be demonstrated and an existing kiln can be modified, low costs relative to other thermal processes can be achieved. This cost is presently estimated at $180-300/ton based on the above concept. This figure includes fuel costs, equipment modifications, a rental fee, and other operating costs.

Extraction/Treatment

Extraction of dioxin-contaminated soil with appropriate solvents can remove dioxin from soil and allow concentration of dioxin in small quantities of extracts. The dioxin in these extracts can be destroyed by incineration, chemical treatment, or ultraviolet light irradiation.

Experiments by ITE show that three successive batch extractions using three volumes of solvent to one weight of soil reduces the dioxin concentration in soil from 360 ng/g to 4 ng/g, a reduction of greater than 98%. The third extract indicated <1 ng/g, residual dioxin in soil. However, rigorous Soxhlett extraction revealed the 4 ng/g residual concentration. These data confirm literature indications that a fraction of dioxin in soil is bound very tightly.

Important technical parameters that must be addressed are soil variability, selection of solvent, type of extraction equipment, phase separation, and solvent recovery. Estimated costs for a 100 ton/day fixed extraction/photolysis plant are $150-300/ton These costs include excavation, 4-year depreciation of capital, maintenance, utilities, raw materials, labor, and miscellaneous items such as overhead, insurance, etc. Cost does not include final soil disposal.

A major concern about soil extraction is the ability to achieve residual dioxin levels of less than 1 ppb. If that level is unachievable for technical or economic reasons, is there value in reducing the concentration range of dioxin in soil to 1 to 10 ppb?

In Situ Treatment

Destruction of dioxin in soil without soil removal is attractive because there is no need for final soil disposal. Two techniques appear technically feasible.

The first, UV irradiation of soil sprayed with a solubilizing liquid, has been demonstrated at Seveso with sunlight (H. K. Wipf et al., in "Dioxin, Toxicological and Chemical Aspects," F. Cattabeni, A. Cavallaro, G. Galli, eds., Spectrum Publications, Inc., NY, 1978, p. 201-217). ITE is carring out experiments with synthetic UV light. The major questions are rate of reduction, degree of reduction, and environmental impact of reaction products.

If soil contamination is very deep, provisions must be made to plow up or excavate, disk, rake, and spread the soil. Preliminary cost estimates for in situ photo-chemical treatment are $50-250/ton. This estimate includes capital depreciation, chemical, labor, and maintenance costs.

Chemical in-situ treatment is being explored by the U. S. EPA-Cincinnati. The proposed reaction involves displacement of chlorine atoms by alkali-metal alkoxides.

Soil Stabilization

Soil stabilization may be achieved by a number of proprietary procedures. The intent of these methods is to fix the dioxin and reduce its potential for migration. Since dioxin in soil does not appear to migrate, additional reduction in soil permeability and dioxin availability must be defined. At that point, decisions of relative risks and costs will decide the suitability of this procedure.

CHAPTER 5

HEALTH RISK ASSESSMENT

The Division of Health and CDC have been working cooperatively from the early years of work with the dioxin issue and most intensively in the months since July 1982. The primary resource person at CDC has been Dr. Renate Kimbrough. Directly or indirectly, Dr. Kimbrough has been providing the guidance and the scientific aspects of health assessment. A preliminary health risk assessment was provided in December of 1982 to the Missouri Division of Health which concluded that levels greater than 1 ppb in soil pose an unacceptable health risk.

An expert group of consultants has been invited to discuss the theory and process of health risk assessment with CDC and a formal statement will be issued by CDC during the summer of 1983. The final report of the Task Force will have this new material for consideration or inclusion. The Task Force believes that the final health risk assessment methodology should be reserved for that report.

CHAPTER 6

ASSESSMENT OF AVAILABLE TECHNOLOGY

The purpose of this chapter is to provide an in-depth assessment of the various disposal technologies outlined in Chapter 3. Included are recommendations as to which disposal technologies are most likely to be viable and which ones require further study. It must be kept in mind that all of the technologies were described in Chapter 3 strictly on a descriptive basis, with no attempt at relative comparison. This chapter will evaluate those technologies on the basis of applicability to the specific sites, primarily Times Beach and Minker/Stout, and on practicality with respect to degree of development. It should be noted that, at this time, no technology has been demonstrated to destroy dioxin in soil to levels significantly below 1 ppb.

Currently Available Technologies

Following is an assessment of those technologies in which the Task Force considers the process or method of disposal to be available on a commercial scale, and deemed potentially capable of either detoxifying the dioxin contaminated soil, or preventing the release of the contaminant to the environment.

Incineration is considered to be the technology which probably offers a relatively short term permanent solution for dioxin contaminated soil. While data demonstrating destruction to sub-ppb levels is not yet available, it would appear that selection of proper temperatures and residence times would provide a reliable system for detoxification. As with all methods of destruction, it becomes practical only if EPA regulations will permit the treated soil to be treated as non-hazardous waste. Incineration of hazardous waste is common, equipment is commercially available, and controls to ensure environmental safety are well understood. It is recommended that trial burns, in facilities described below, should be made as soon as possible to demonstrate feasibility.

The EPA has at least two facilities which would be capable of performing the required trial burn. One is their mobile incineration system, which would be brought in and set up directly on the chosen site. Several problems exist with this approach, primarily because of the length of time it would take to set up the unit and arrange the necessary permits. Siting requirements such as electricity, water, and fuel would be difficult and expensive to set up. The mobile incineration unit is not recommended as a means of conducting the test burn, nor is it recommended as an end solution to the problem.

The second EPA facility is the newly constructed Pine Bluff incineration system in Arkansas. This incinerator is designated as a research facility, and has recently been granted the necessary permits to operate. It is understood that this unit would be capable of conducting a test burn for dioxin destruction. It is recommended that an attempt be made to obtain the highest priority on the test list for the facility and, once placed on list, all necessary research permits be expedited.

The Task Force believes that information resulting from the test burns, using various soils having different concentrations of contamination, will be useful in determining the degree of dioxin destruction that incineration can provide, and the residual dioxin left in the resultant ash. This data would permit negotiation with EPA as to whether this ash must be landfilled as a hazardous waste, or can be considered a non-hazardous material.

Ultra violet destruction of dioxin has been demonstrated in certain applications on a commercial scale. However, it has also been demonstrated that irradiation time becomes excessive as concentration of dioxin decreases into the ppb range. Therefore, it is not considered to be a viable solution to the problem of dioxin in soil at low concentrations, but may be useful in destroying dioxin in extracts.

Solvent extraction followed by incineration or other methods of destruction remains a possible solution to removal of dioxin from soil. Exhaustive continuous extraction is used in laboratory analysis of dioxin in soil. However, large scale extractions would probably require batch treatment with each stage of extraction removing a fixed fraction of the remaining dioxin, presenting the same problem as UV destruction as concentration of dioxin decreases. It is recommended that further study be done, and this technology is discussed further on page 71.

In place stabilization using grout curtains and organic or inorganic fixatives may be an acceptable final solution for some Missouri sites, but is not recommended for the Times Beach and Minker/Stout sites for the following reasons. In the case of the Minker/Stout site, the geology of the site is poorly suited to this type of containment effort. A layer of highly fractured limestone above sandstone makes complete elimination of groundwater movement through the contaminated area difficult to guarantee. In the case of Times Beach, the contamination is predominantly on and along the roads. But in order to ensure containment of the contaminated soil, the entire town would have to be encircled by the grout curtain, making this an inefficient means of containment. However, the concept of grout curtain containment is in use today, and may be a viable alternative at sites other than Times Beach and Minker/Stout, depending on site specific geology.

Although organic and inorganic fixatives are considered methods of in place stabilization, further study is needed. These methods will be discussed in further detail on page 71.

On-site storage, either in below ground cells or above ground vaults, was evaluated. Below ground cells do not provide an appropriate option. This option would involve on-site excavation and subsequent reburial of the contaminated soil as well as long term monitoring at each of the sites.

Above ground concrete storage vaults have some advantages over below ground storage in that monitoring requirements are more easily met, and any leaks or faults in the structure are more easily detected and repaired. This is not a recommended option, except under special circumstances, because of logistical problems in permitting, monitoring and maintaining 30 or more individual sites. Special circumstances, as mentioned above, could involve the consolidation and storage of contaminated soils from a number of smaller sites at one of the larger, centrally located sites in the area, probably as interim storage in conjunction with a treatment scheme.

The Task Force discussed the possibility of transport to a secure landfill offsite as a remedial action for the Times Beach and Minker/Stout sites. There are existing outstate landfills which could possibly be considered, but landfilling at any of them is not a viable option at this time, due to the large volumes of soil involved, and the distance that this volume of soil would have to be transported. The Task Force wishes to emphasize that landfilling in this manner should only be considered as a last resort for these sites, if all other options for remedial action have failed.

The final option which seemed to be viable was that of in place treatment of the contaminated soil. Most of the technologies grouped into this option are still in the developmental stages, and will be discussed on page 72.

Implementation Considerations

The Task Force believes that in order to implement many of the above mentioned technologies, a centrally-located hazardous waste storage-treatment facility should be considered. A study should be done to resolve where such a facility could be located and whether it should be state owned.

Recommendations for Further Study

Certain of the technologies discussed in Chapter 3 are considered to have merit, but have not been developed to the point where they can be considered viable disposal techniques. Some are functioning at lab scale. Some are operating commercially for wastes other than dioxins, and some have not yet been tested. However, each of these technologies is worth pursuing. Further research and testing should be done on each of the following technologies.

Fixatives

Under the option of in place stabilization, two types of surface fixatives exist: inorganic substances and organic polymers. Further studies on impermeability and long-term stability of these types of fixatives should be conducted.

Solvent Extraction

The concept of solvent extraction is well established and in wide use. However, the feasibility of this process to remove dioxin from contaminated soils to sub-ppb levels has yet to be demonstrated. In an effort to determine if solvent extraction can reduce the level of contamination to environmentally acceptable levels, the following studies are recommended.

An appropriate solvent should be identified. The ideal solvent must have a large solubility for dioxin and a large solvent-soil distribution coefficient, must be easily removable from the soil, and must be non-toxic because a portion of the solvent will probably remain trapped with the soil even after drying. The solvent studies should include supercritical fluids as well as more common solvents.

Additional studies should address the destruction of dioxin in the solvent after the extraction process is completed. Some of the methods which have been proposed are destruction by the addition of a chemical reagent, incineration of the solvent, and destruction of the dioxin using UV photolysis.

In-Place Treatment

The option of in-place treatment is important if a method of decontamination can be developed whereby the contaminated soil would not need to be excavated or moved. In-place treatment offers the advantage of minimal risk to workers and the environment and probably would be the least expensive method. Specific study of the following forms of in-place treatment is recommended.

Biodegradation is already in use on a commercial scale for the detoxification of certain wastes. However, researchers have not yet been able to isolate or genetically engineer organisms which are capable of degrading dioxin. The possibility also exists that an organism may be found which can metabolize dioxin in a controlled environment, in which case the contaminated soil could be excavated and placed in the controlled environment. This research is of the utmost importance and should continue.

Other methods of in-place treatment which merit further study are ionizing radiation, chemical treatment, and any other method which shows possibility of destroying or stabilizing the dioxin molecule.

Recognizing that the methods listed above may not be the only ones which should be considered as possible future options for remedial action, the Task Force welcomes and encourages any new technology which holds the promise of solving Missouri's dioxin problems.

CHAPTER 7

RECOMMENDATIONS FOR FURTHER RESEARCH

This chapter attempts to focus on research needs which are necessary to make informed decisions about remedial action. The two major areas of concern in which data is lacking are health studies and the behavior of dioxin in the environment.

Many animal studies have been done which indicate that widely varying levels of toxicity demonstrated by different animal species. Much debate has been heard on how to extrapolate the animal studies on toxicity to humans. Research on humans has not clearly indicated what level of exposure can cause toxic effects.

Research and accidental exposure of humans has shown definite acute effects of dioxin such as chloracne, liver disease and porphyria cutanea tarda. Birth defects have been reported in some studies but not confirmed in others. Long term effects such as cancer are still debatable, although limited data on soft tissue sarcomas are suggestive. Therefore, continuing research on the human effects of dioxin is recommended.

A related issue is that of the health of residents who have lived at contaminated sites for a number of years. Since many questions remain about the long term health effects that dioxin may have on these people, the Task Force recommends consideration of continued and broadened health studies be conducted on these people.

Further studies on the behavior of dioxin in the environment are needed. Research should be conducted to determine the possibility of dioxin leaching from contaminated soil into groundwater over a period of years. Related work is necessary to determine if dioxin found in aquatic organisms in surface waters near contaminated sites is due to leaching of dioxin directly into surface waters, or to the transport of contaminated soils as sediment into the water. Since the presence of dioxin has been impossible to detect in water, some type of concentrator should be developed, such as a resin or charcoal, or a quantitative bioindicator. Further research into background levels of dioxin in aquatic organisms of surface waters away from the contaminated sites is recommended.

Research should be conducted regarding the persistence of dioxin in the environment, particularly as a contaminant in soil. The use of the term "half life" with respect to dioxin in the environment is erroneous, and a systematic attempt should be made to clarify the mechanisms of dioxin disappearance in the environment.

Possibly the most important topic for additional study is that of the bioavailability of dioxin in soil. Research data available has indicated that dioxin in soil exhibits a binding phenomena, in that the dioxin molecules adhere very tightly to the soil particles. Further research may indicate whether or not the dioxin is so tightly bound to the soil that it is not available to the organism that comes in contact with the soil, whether that contact is dermal or by ingestion.

The Task Force recognizes the need for research and resources to help solve the problems that Missouri faces. This research also will assist in addressing and solving national problems. There already exists in Missouri the necessary expertise and research facilities that could be equipped to perform the necessary studies, if properly funded.

CHAPTER 8

SPECIFIC SITE RECOMMENDATIONS

This chapter deals with recommendations of the Task Force for the Times Beach and Minker/Stout sites, the two sites which have had the highest priority. The Task Force will submit recommendations for other sites in its final report. Certain of the comments to follow are general in nature, and could be applied to both Times Beach and Minker/Stout. These comments will be addressed first. Comments more specific to the individual sites will be discussed in separate sections.

Although one cannot be absolutely sure what actual exposure or risk is experienced by any individual Missouri citizen, the public health recommendations of separating the people from the soil contaminated with greater than 1 ppb appear to be reasonable and prudent measures. It must also be assured that the sites themselves are stable and that no significant movement of either dioxin or contaminated soil is occurring. Actions already taken at the two sites, namely the temporary relocation and buyout, will serve to alleviate one of the main concerns of the Task Force, namely human exposure at the sites. These measures have provided more time to study the remedial actions and to make informed decisions about those remedial actions. It is of prime importance that the buyout be expedited. Once that is accomplished, the Task Force recommends that access to the sites be completely restricted by posting signs, erecting barriers, and any other measures necessary to keep unauthorized persons away from the contaminated soil. This would come under the heading of initial remedial action.

The Task Force recommends a program of additional sampling to determine the nature and extent of the problem. This sampling should include both surface water and ground water monitoring to determine whether the contamination is migrating, either by direct leaching from the soil, or by sediment transport. A concentrator such as charcoal, resin, or a quantitative bioindicator, should be used to detect any low levels of dioxin in the water.

In studying the information available about the two sites, the Task Force concludes that the Minker/Stout site needs priority over Times Beach, at least in implementing initial remedial action, because Minker/Stout is an unstable site with respect to migration of contaminated soils whereas Times Beach appears to be more stable. These concerns are addressed in greater detail in the following sections.

The adequacy of the health studies performed to date should be evaluated.

Minker/Stout

The Task Force recommends that the buyout for Minker/Stout be expedited. Information indicates that this site is unstable with respect to migration of soils, hence the priority status for Minker/Stout. Immediate action should be taken to stop the erosion which is occurring in the fill area and washing across the site into Romaine Creek. Short term measures such as extending the drain pipe out from the culvert and past the fill area, along with covering eroded areas with sod or other natural cover may be sufficient to stop most or all of the erosion of contaminated soil from the fill area. Thereafter, monitoring of surface and groundwater should be done in the site area to determine if erosion of contaminated soil has been eliminated.

While the short term measures outlined above should reduce soil erosion, the site must still be considered an unstable one because of extremely poor site geology, consisting of a layer of highly fractured limestone over sandstone. The Task Force recommends that planning for final remedial action for this site be continued with all deliberate speed.

Times Beach

The buyout should be expedited in order to remove the residents from the site and reduce exposure to the contaminated soil. Access to the site should then be limited to further reduce exposure. Evidence indicates that Times Beach is a relatively stable site. Therefore, no further immediate remedial actions are recommended at this time. The Task Force recommends that additional soil sampling be done to determine more specifically the areas and levels of contamination within the site. Sampling of surface and groundwater should be done to determine if the contamination is spreading due to leaching or sediment transport. If the results of these studies should indicate that significant contaminant migration is occurring, then additional interim remedial action should be undertaken. In any event, the results of the sampling can be used to aid in planning for final remedial action at the site.

APPENDIX 1

AGENDA

DIOXIN TASK FORCE MEETING

February 23, 1983

Conference Room, Department of Natural Resources
1915 Southridge
Jefferson City, Missouri

1. 10:00 Introduction of Task Force Members........Fred Lafser, DNR
Governor's Remarks to Task Force

2. 10:30 Discussion, Scope and Magnitude of Dioxin Problems in Missouri:

(a) Location and Levels of Contamination......Fred Lafser, DNR

(b) Health Effects......Robert Hotchkiss, DOH

12:00 Lunch

3. 1:30 Summary of Solutions Proposed by Interested Companies......DNR Staff

4. 1:45 EPA Role

5. 2:15 Discussion of Task Force Activities and Assignment of Sub-Tasks

6. 3:00 Discussion of Schedule of Meetings

7. 3:15 Adjourn

DIOXIN TASK FORCE SITE TOUR 3-17-83

ITINERARY

8:00 a.m.	Arrive - lobby of Airport Marriott
8:15 a.m.	Leave Marriott
9:00 a.m.	Arrive at Shenadoah Stables
9:30 a.m.	Leave Shenadoah Stables
10:30 a.m.	Arrive at Methodist Church (drive by)
11:00 a.m.	Arrive at Times Beach
11:45 a.m.	Leave Times Beach
12:00-1:30 p.m.	Lunch at Stratford House - Fenton
2:00 p.m.	Bubbling Springs Stables (drive by) (Cashel Site)
2:15 p.m.	Arrive Minker & Stout Sites (Sullens Site)
3:00 p.m.	Leave Minker & Stout Sites
3:30 p.m.	Jones Truck Lines (drive by)
3:40 p.m.	Overnite Transfer, Inc. (drive by)
4:00 p.m.	Southern Cross Lumber (drive by)
4:30 p.m.	Return to Marriott parking lot

AGENDA
(Revised)

DIOXIN TASK FORCE MEETING

March 30, 1983

Conference Room, Department of Natural Resources
1915 Southridge
Jefferson City, Missouri

1. 10:00 Approval of previous meeting minutes....February 23 Meeting

2. 10:15 Explanation of Cattle Deaths on Bill Davis Farm....Dr. Thomas Satalowich, DVM

3. 10:30 Evaluation of Dioxin Disposal Technologies and Costs....CH_2M - Greg Peterson, John W. Lee, Bill Byers

1:00 Lunch

4. 2:00 Discussion of Superfund Procedures - EPA

5. 3:00 Summary of proposals received to date by the Waste Management Program from firms interested in dioxin cleanup....Beth Rice, WMP

6. 5:00 Future Meeting Agendas....April 14 and 28 meetings

7. 5:30 Adjourn

AGENDA
(Revised)
DIOXIN TASK FORCE MEETING

April 13, 1983

Second Floor Conference Room
Division of Health-Laboratory Building
307 West McCarty
Jefferson City, Missouri

1. 3:00 - VIDEO TAPE SERIES

   Tape 1
   "Introductory Discussion of Dioxin Problem in Missouri"
   by Henry Falk, M.D., CDC, Atlanta, Georgia

   Tape 2
   "Animal and Human Health Effects of 2,3,7,8 Tetrachlorodibenzo Dioxin - An Overview"
   by Renate Kimbrough, M.D., CDC, Atlanta, Georgia

2. 5:00 - Dinner

   Conclusion of Video Tape Series (Optional)

April 14, 1983

Department of Natural Resources Conference Room
1915 Southridge Drive
Jefferson City, Missouri

1. Approval of previous meeting minutes....March 30 meeting

2. 8:30 - William G. Dunagin, M.D.
   Division of Dermatology M173
   University of Missouri
   Health Science Center
   Columbia, Missouri 65212

3. 10:00 - Jay Murray, Ph.D.
   Syntex Corporation
   3401 Hillview Avenue
   Palo Alto, California 94304

4. 11:00 - David Stallings, Ph.D.
   Chief Chemist
   Columbia National Fisheries
   Research Lab
   U.S. Fish and Wildlife Service
   Route 1
   Columbia, Missouri 65201

5. 12:00 - Lunch

6. 1:30 - Alvin L. Young, Ph.D.
Major, U.S. Air Force
Acting Chief of Research Section
Agent Orange Project Office
810 Vermont Ave., N.W.
Washington, D.C. 20420

7. 3:00 - Dr. Robert Neal, President
Chemical Industry Institute of Toxicology
Research Triangle Park
Raleigh-Durham, North Carolina 27709

8. 4:00 - Stephen M. Ayres, M.D.
Department of Internal Medicine
St. Louis University Medical School
1325 South Grand Boulevard
St. Louis, Missouri 63104

9. 5:00 - Future Meeting Agendas....April 28 and May 12 Meetings

10. 5:15 - Adjourn

AGENDA

DIOXIN TASK FORCE MEETING

April 28, 1983

Department of Natural Resources Conference Room
1915 Southridge Drive
Jefferson City, Missouri

I. 9:00 a.m. Appoval of previous meeting minutes...March 30 and April 14 meetings

II. 9:15 a.m. Speakers:

(1)	Phillip C. Kearney, Ph.D. Chief, Pesticide Degradation Lab Agricultural Environmental Quality Inst. Agricultural Research Center, USDA Beltsville, Maryland	Fate of dioxin in the environment; plant, fish and animal studies
(2)	Jurgen H. Exner, Ph.D. Manager, Engineering/Research and Development IT Enviroscience Knoxville, Tennessee	Behavior of dioxin in soils-degradation
(3)	Henry Falk, M.D. Chief, Special Studies Branch Chronic Disease Division Center for Environmental Health Centers for Disease Control Atlanta, Georgia	Human health effects of dioxin

III. 12:00 Lunch - catered in by Nick's Homestead

IV. 1:00 p.m. Slide presentation/discussion of southwest sites:
- (1) Neosho site - Dwight Douglas
- (2) Denny Farm site - Ray Forrester
- (3) Spring River - Ron Crunkilton
  Dr. Jim Whitley
  Department of Conservation

V. 2:30 p.m. Discussion with EPA Representative
- (1) New RCRA rule on dioxin
- (2) Coordination with CH2M-Hill feasibility study

VI. 3:00 p.m. Discussion of interim report due June 1, 1983

VII. 5:00 p.m. Future meeting agendas...May 12 and May 26 meetings

VIII. 5:30 p.m. Adjourn

TENTATIVE AGENDA

DIOXIN TASK FORCE MEETING

May 12, 1983

Ramada Inn - Roanoke Room
1510 Jefferson Street
Jefferson City, Missouri

I. 9:00 a.m. Approval of minutes...April 28 meeting

II. 9:15 a.m. Presentations by firms submitting preliminary remedial action proposals

(1).	Midland Ross Corporation 2375 Dorr Street Toledo, Ohio	incineration
(2).	Chemical Waste Management Waste Management, Inc. 3003 Butterfield Road Oak Brook, Illinois	extraction, incineration of solvent, landfilling of soil
(3).	Critical Fluids Systems, Inc. Subsidiary, Arthur D. Little, Inc. 25 Acorn Park Cambridge, Mass.	extraction by supercritical solvent

15 Minute Break

(4).	Acurex Waste Technologies, Inc. Subsidiary, Acurex Corp. 8074 Beechmont Avenue Cincinnati, Ohio	extraction, chemical treatment of solvent
(5).	SCA Chemical Services, Inc. 1836 North Broadway St. Louis, Missouri	SCA doesn't wish to make a presentation at this time, but would like to make themselves available to answer questions about their proposal

12:00 Lunch to be arranged by Ramada Inn

II. 1:00 p.m. (Continued)

(6).	IT Enviroscience 312 Directors Drive Knoxville, Tennessee	thermal destruction; extraction; in situ treatment
(7)	Rollins Environmental Services, Inc. P. O. Box 609 Deer Park, Texas	comparison of incineration, extraction, and landfilling

III. 2:00 p.m. Discussion of Initial Draft Interim Report

3:00 p.m. 15 Minute Break

IV. 5:00 p.m. Adjourn

May 13, 1983

I. 9:00 a.m. Further Discussion of Initial Draft Interim Report

10:30 a.m. 15 Minute break

12:00 p.m. Lunch to be arranged by Ramada Inn

II. 1:00 p.m. Further Discussion of Initial Draft Interim Report

III. 4:00 p.m. Future meeting agendas...May 26 and June 16 meetings

IV. 4:30 p.m. Adjourn

AGENDA

DIOXIN TASK FORCE MEETING

May 26, 1983
Department of Natural Resources
Conference Room
1915 Southridge Drive
Jefferson City, Missouri

I.	9:00 a.m.	Approval of Previous Meeting Minutes...May 12 and 13 Meeting	
II.	9:15 a.m.	Discussion of Final Draft Interim Report	
III.	10:30 a.m.	15 Minute Break	
IV.	11:45 a.m.	Lunch at Nicks Homestead

APPENDIX II

DIOXIN TASK FORCE MEETING

February 23, 1983

Department of Natural Resources' Conference Room
Jefferson City, Missouri

MEMBERS PRESENT

James Finch, Chairman
Dwight Douglas
Ray Forrester
Perry King
Carl Marienfeld
Sharon Rogers
George Roush
James Shaddy
Betty Wilson

Robert Powell was not present. Claudia Spener represented Dr. Powell.

ORDER OF BUSINESS

The meeting came to order at 10:10 a.m.

Missouri Department of Natural Resources' Director, Fred Lafser, introduced each Dioxin Task Force member. He also introduced Dr. Robert Hotchkiss, Division of Health; Bill Rice, U.S. Environmental Protection Agency; and several DNR staff members.

Governor Christopher S. Bond then welcomed the task force members and thanked them for serving on the task force. Governor Bond presented some background information on what has happened and various steps taken by him since the dioxin issue began last year. The Governor directed the task force to study all angles of the problem and to study any alternatives for eliminating the danger of dioxin and to recommend the most safe, practical and technologically sound solutions. He also presented a five-point dioxin program which he has recommended to the Missouri General Assembly (please refer to the transcript of the Governor's remarks previously sent to you).

Dr. David Bedan, Director of the Waste Management Program, then gave a brief history of the contamination episode. He presented a chart, produced by EPA, that showed the origination of the waste from the old NEPACCO plant in Verona, Missouri and showed how the waste got to the different sites. Dr. Bedan then presented a map of the 22 confirmed sites and gave a brief summary description of each site. He noted there were three errors in the summary description.

1. Minker Site - The range of concentration should be from .3-300 ppb instead of 900 ppb.
2. Times Beach Site - It should be 300 ppb instead of 100 ppb.
3. IML Lines Site - This should be changed to the Overnite Transfer Company.

Dr. Robert Hotchkiss, Director of the Division of Health, then provided a summary of the health effects that dioxin has had on experimental animals and situations of human exposure. He also provided a summary of different studies relating to the cancer-causing potential of human exposure to dioxin. He stated there is a study of the possible health effects associated with the actual real exposure to dioxin here in Missouri that is in the process of being carried out. There have been 146 dermatological exams, 112 comprehensive medical exams, and over 850 extensive medical questionnaires involved in this study.

Dr. Denny Donnell, also of the Division of Health, summarized a talk given by Dr. Marilyn Fingerhut to the physicians at the St. Louis Medical Society which referred to Swedish and American studies concerning questions of the cancer-causing potential of human exposure to dioxin.

Representative Bob Feigenbaum then discussed three bills that have come out of public hearings and meetings held since October. One of the bills is the Superfund which would provide funding in the amount of $6.8 million for an ongoing cleanup measure, not only for the dioxin sites but also for future hazardous waste cleanups. Of the $6.8 million, $5 million would come from generators, $1.5 million from transporters, and the remainder from landfill operators. This Superfund money would only be used when the responsible party could not be found. The second bill is the Cancer Registry which will allow the state to correlate any high levels of different types of cancer to the hazardous waste sites. This information could then be used to convince EPA and federal agencies that there is a problem at a particular site. The third bill is the Workers' Right to Know which doesn't deal just with the dioxin problem.

Joe Jansen of the Waste Management Program then gave a summary of some of the disposal methods and proposals that the department has received from various companies in the waste management business indicating their desire to help with the dioxin problem. Mr. Jansen then presented a chart which gave some very preliminary and very general cost estimates of the different alternatives that the department thinks might work for clean up at the various sites. These were very rough estimates.

Bill Rice, U.S. Environmental Protection Agency, then discussed EPA's role and activities with the dioxin problem. First EPA or the Missouri Department of Natural Resources investigates the sites to determine whether there is a likelihood that dioxin is present. They would send out sampling teams and have the samples analyzed either through their own laboratories or through contracted laboratories. They would then decide from this initial sampling if additional sampling is required. After the problem has been characterized, they can then take legal action against property owners or companies may propose to clean up the site themselves or the sites can be put on the National Priority List.

FUTURE MEETINGS

It was decided that the next meeting would include visits to some of the dioxin sites in the St. Louis area. The task force members are to meet in the lobby of the airport Marriott at 8:00 a.m. on Thursday, March 17. From there they would travel by bus to various dioxin sites in the area. After this trip it would then be decided whether trips to sites in southwestern Missouri would be beneficial.

The following meeting dates were also decided upon:

Wednesday, March 30
Thursday, April 14
Thursday, April 28
Thursday, May 12
Thursday, May 26

These meetings will be held in the Department of Natural Resources' conference room and will begin at 9:00 a.m. and run until 4:00 p.m. with an hour for lunch from 12:00 to 1:00.

OTHER BUSINESS

There was some discussion on task force activities and assignment of subtasks. It was suggested that after the site visits and gathering of some background information on various sites that an attempt be made to group the sites by some criteria and prioritize them for the first report and have various people work on various aspects (landfilling, incineration, health subtask, disposal sub-task). It was suggested that the members think about this and give suggestions on who would be particularly desirable and set up subtasks at the next meeting.

Joe Jansen then distributed expense account forms and explained to the members how to fill out the forms for reimbursement.

Some suggestions were then made on various speakers to hear at future task force meetings. It was decided that the members should write DNR about any suggestions they have and have the department make arrangements for the speakers. The contact person is to be Dr. David Bedan, Department of Natural Resources, Waste Management Program, P.O. Box 1368, Jefferson City, MO 65102 (phone: 314-751-3241). Regarding speakers on health related issues the contact person is to be Dr. Denny Donnell, Department of Social Services, Division of Health, P.O. Box 570, Jefferson City, MO 65102 (phone: 314-751-2713).

The meeting was adjourned at 3:35 p.m.

Betty Wilson

ORDER OF BUSINESS

The meeting was called to order at 10:00 a.m.

There was a correction to the February 23, 1983 minutes. Where the Minker Site and Times Beach Site were listed at the bottom of page 1, ppm should have been ppb. Dwight Douglas then made a motion to approve the minutes with corrections. They were approved.

Dr. Thomas Satalowich, DVM, Missouri Division of Health, discussed the analyses of the cattle deaths on the Bill Davis farm. He stated the milk had been tested for dioxin approximately four times and turned out negative each time. Mr. Davis also had brought cattle that had died on his farm to the lab to be tested, and these tests also turned out negative. The cattle had a form of infectious bovine leukemia that could not be detected as dioxin related.

Mr. Robert Morby, U.S. Environmental Protection Agency, then discussed Superfund procedures. He discussed the three principal types of action: immediate removal, planned removal, and remedial action. He also discussed the difference between Cooperative Agreement and State Contract.

David Bedan then briefly talked about the "Report on Potential and Confirmed Uncontrolled Hazardous Waste Sites in Missouri" that had been released the previous day, March 29.

Dr. Denny Donnell, Missouri Division of Health, discussed the tentative plan for speakers for the April 14, 1983 meeting. The five speakers that are available are:

1. Bill Dunagin - UMC Dermatologist
2. Jay Murray - Syntex, Palo Alto, California
3. Alvin Young - Veteran's Administration, Washington, D.C.
4. Robert Neal - Chemical Industrial Institute of Toxicology, North Carolina
5. Stephen Ayres - Chief of Internal Medicine, St. Louis University Hospital

Some of the other suggested speakers who could not come until a later date or could not come at all are:

1. Samuel Epstein - University of Illinois at Chicago - Is not willing to come.
2. Ellen Silbergeld - Environmental Defense Fund, Washington, D.C. - Would be available on April 27 or 28.
3. Ray Susskind - Institute of Environmental Health, University of Cincinnati - Would not be available until early July.
4. Dr. Kimbrough - CDC - Would not be available for several weeks.

Dr. Donnell suggested the Task Force might want to see the video tapes of presentations to the St. Louis Medical Society, including a talk given by Dr. Marilyn Fingerhut concerning questions of the cancer-causing potential of human exposure to dioxin.

It was then suggested that the Task Force view the video tapes on the afternoon of April 13 starting at 3:00, breaking for dinner around 5:00 or 5:30, and reconvening again in the evening around 7:30 or 8:00 p.m.

Greg Peterson and Bill Byers from CH_2M Hill then gave a presentation on the evaluation of dioxin disposal technologies and costs for the Minker/Stout Site. They discussed the advantages and disadvantages of six different options. The six options are:

1. Securing in place
2. Consolidation on site
3. Securing off site
4. Incineration
5. Extraction
6. Storage until new technology is developed.

Beth Rice, Waste Management Program, then gave a summary of the proposals received to date by the Waste Management Program from firms interested in dioxin cleanup. Preliminary proposals were requested from all the firms that contacted us. At the present time the program has received two proposals.

A sixth person was then added to the list of speakers for April 14. Dr. Carnow of the University of Illinois at Chicago will be speaking for Dr. Epstein. It was decided since there would be a sixth speaker to start the April 14 meeting at 8:30 a.m. with three speakers in the morning and three in the afternoon. There would be an hour for task force discussion at the end of the day.

Some suggestions were made by Dave Bedan and Robert Schreiber for topics for the April 28 meeting:

1. Presentations from companies interested in dioxin cleanup.
2. Presentations from labs involved in testing for dioxin.
3. Presentations from people involved in studies concerning the effects of dioxin on animals
4. Someone from Fish & Wildlife Research Center in Columbia.

There was then some discussion on whether the Task Force should hear from specific companies about their proposals.

Dwight Douglas then questioned whether the Task Force wanted to see the video presentation from the wastewater school at Neosho. It was decided to see these slides and video presentation at the April 28 meeting. The Task Force would then decide whether they should visit the sites in southwestern Missouri, since complaints had been received saying the dioxin problem was being addressed more in the St. Louis area than in the southwestern Missouri area.

The meeting was adjourned at 4:20 p.m.

ORDER OF BUSINESS

The Task Force met the previous afternoon, April 13, 1983, at 3:00 p.m. at the Division of Health Laboratory Building to view three video tapes. One of the tapes was titled "Introductory Discussion of Dioxin Problem in Missouri" by Henry Falk, M.D., CDC, Atlanta, Georgia. The second tape was titled "Animal and Human Health Effects of 2,3,7,8 Tetrachlorodibenzo Dioxin - An Overview" by Renate Kimbrough, M.D., CDC, Atlanta, Georgia. The third tape was titled "Epidemiology of Sarcomas" by Marilyn Fingerhut, Ph.D.

The meeting on April 14 was called to order at 8:40 a.m. at the Department of Natural Resources.

The first speaker was Dr. William G. Dunagin, M.D., Division of Dermatology, University of Missouri Health Science Center, Columbia, Missouri. Dr. Dunagin made the following conclusions:

1. Chloracne is the most sensitive indicator of dioxin exposure in humans.
2. There do not appear to be any cases of chloracne in Missouri.
3. Dermal absorption of dioxin from soil in Missouri is about one million times less than the amount necessary to induce toxicity.
4. In animal studies the dose of dioxin necessary to cause cancer is near or about the same dose which causes direct toxicity.

The next speaker was Dr. Jay Murray, Ph.D., Syntex Corporation, Palo Alto, California. Dr. Murray discussed some of the reproductive and other toxic effects of dioxin seen in laboratory animals. He also summarized some of the human health effects of dioxin including chloracne, liver effects, neuromuscular symptoms, altered porphyrin metabolism, and a number of subjective symptoms. Dr. Murray also discussed a study of an industrial accident that occurred at a Monsanto Plant in 1949 involving overexposure to TCDD and another industrial accident that occurred in Seveso, Italy.

The next speaker was Dr. David Stalling, Ph.D., Chief Chemist, Columbia National Fisheries Research Lab, U.S. Fish and Wildlife Service, Columbia, Missouri. Dr. Stalling summarized some of the work being done in various parts of the country on analysis for dioxin. He also discussed dibenzofurans which are very similar in structure and behavior to dioxins and are often found along with dioxins.

At lunch the Task Force discussed possible agenda items for the future task force meetings.

The next speaker was Dr. Robert Neal, President, Chemical Industry Institute of Toxicology, Research Triangle Park, Raleigh-Durham, North Carolina. Dr. Neal discussed different situations involving human poisoning with TCDD. He also presented a table showing the results of studies in Sweden, Finland, United States and Germany of humans exposed to TCDD. Dr. Neal stated that studies show that TCDD does produce cancer in mice and rats; however, there is no cause and effect relation between TCDD exposure and cancer yet shown in man but this needs to be investigated further.

The next speaker was Dr. Alvin L. Young, Ph.D., Major, U.S. Air Force, Acting Chief of Research Section, Agent Orange Project Office, Washington, D.C. Dr. Young discussed a series of studies conducted at the Eglin Air Force Base in Florida where a herbicide containing TCDD was sprayed. Studies were done on plants at the site and on deer, rabbits, opossums, beach mice, insects, snakes and birds at the site. TCDD was not found in the deer, opossums or rabbits. However, TCDD was found in beach mice that were around the edges of the water site. TCDD was also found in the insects, in the snakes, in the meadowlark birds and in fish at the bottom of the pond on site. Studies are also being conducted on herbicide levels on Johnston Island and at Gulfport, Mississippi. Dr. Young also discussed other studies being conducted including a study in St. Louis, Missouri on identical twins where one twin is a Vietnam veteran and the other twin served in the military but not in Vietnam.

The final speaker was Dr. Stephen M. Ayres, M.D., Department of Internal Medicine, St. Louis University Medical School, St. Louis, Missouri. Dr. Ayres discussed some of the major and minor criteria for the diagnosis of dioxin associated illnesses. He also recommended that the state pass legislation dealing with hazardous waste, particularly Representative Bob Feigenbaum's bill dealing with funding.

Sharon Rogers and Betty Wilson reported they had both received calls from a Mr. Murray Abrahamson who lives across from the Minker site. He expressed concern for the health and welfare of his family.

The meeting was adjourned at approximately 5:00 p.m.

ORDER OF BUSINESS

The meeting was called to order at 9:10 a.m.

Dwight Douglas moved to approve the March 30, 1983 and the April 14, 1983 minutes as submitted. Robert Powell seconded the motion. Both sets of minutes were approved as submitted.

The first speaker was Dr. Phillip C. Kearney, Chief, Pesticide Degradation Lab, Agricultural Environmental Quality Institute, Agricultural Research Center, USDA, Beltsville, Maryland. Dr. Kearney first discussed different processes which affect pesticides in the environment, but more specifically the molecule TCDD. The different processes discussed were: sunlight or photochemical degradation, chemical degradation, microbiological degradation or microbial metabolism, leaching, adsorption of a pesticide or TCDD to a soil particle, uptake by plants, and volatility. Dr. Kearney then discussed studies that have been done on a terrestrial ecosystem. This is a way of looking at the life history of a molecule such as TCDD and what happens to it. He then discussed bioaccumulation of TCDD in the aquatic environment, bioaccumulation in farm animals and bioaccumulation from oral and dermal exposure to TCDD in rats. Dr. Kearney referred to a paper by Poiger and Schlatter, Swiss Federal Institute at Zurich, which discussed different types of studies done on rats and compared the different levels of accumulation of TCDD in the livers of these animals. Dr. Kearney then discussed his experiences in Seveso, Italy during the summer of 1976. He was asked to devise a decontamination plan for the Seveso area.

The next speaker was Dr. Jurgen H. Exner, Manager, Engineering/Research and Development, IT Enviroscience, Knoxville, Tennessee. Dr. Exner discussed some of the dioxin treatment techniques and the kinds of problems faced in trying to develop a treatment process. He illustrated some of these problems by giving a brief description of their efforts at Verona. Dr. Exner then discussed the chemistry of dioxin in the soil. He also discussed some of the options that exist for treating dioxin in the soil (e.g. extraction, incineration, etc.).

The next speaker was Dr. Henry Falk, Chief, Special Studies Branch, Chronic Disease Division, Center for Environmental Health, Centers for Disease Control, Atlanta, Georgia. Dr. Falk discussed CDC's roles in the dioxin episode. CDC has been working with EPA in terms of evaluation and interpretation of EPA environmental data as it becomes available and also working with them on the quality assurance aspects of the environmental data. CDC has also worked closely with the Missouri Division of Health in evaluating situations and making public health decisions. Three other points that Dr. Falk also discussed were:

1. The extreme potency of dioxin in a variety of animal species.
2. There is a variability within species and there is a variability between the dose that will cause an acute effect, the dose that will cause a chronic effect, and the dose that one would consider safe.
3. There is a body of knowledge about the effects of dioxin in people that comes mostly from occupational settings.

Dr. Falk also outlined the risk assessment process and the analysis that led to the selection of the 1 ppb level of dioxin in the soil as a level which could be used publically in terms of making decisions about different sites.

Dwight Douglas then gave a slide presentation on some of the dioxin sites in southwest Missouri. He briefly explained the geography of the area including the Neosho site, the community of Verona and the Spring River. The three locations of the contaminated sites are: (1) the digester at the sewage treatment plant, (2) the Water and Wastewater Technical School site, and (3) the Bunker site.

Ray Forrester then provided a 17-minute video tape titled "Toxic Cleanup" that gave a brief synopsis of the Denney Farm Site action which was conducted by Syntex under the supervision of EPA.

Dr. Jim Whitley, Chief of Fisheries Research, Missouri Department of Conservation, briefly discussed studies done in the 1950's and 1960's on aquatic life in the Spring River. The Department of Conservation has also recently collected fish from the Spring River and sampled them for dioxin. Ron Crunkilton, Water Quality Biologist, then discussed the economic importance of the Spring River in southwest Missouri. He stated the river contains one of the most diverse fish populations in the state. He also stated that the Food and Drug Administration advisory levels on dioxin have been set. Mr. Crunkilton discussed averages and ranges of dioxin found in different kinds of fish in the Spring River. As a result of some of these values, the State of Missouri has issued an advisory for people to limit their consumption of fish from the entire Spring River.

There was then some brief discussion about the upcoming meetings in May. It was decided that there would be a two-day session on May 12 and 13. The second day would be for the purpose of working on the interim report due June 1. It was also decided to change the May 26 meeting to May 23 if Dr. Renate Kimbrough would be able to speak on the 23rd.

Robert Morby, U.S. Environmental Protection Agency, then discussed a new rule proposed by EPA that was published in the Federal Register on April 4, 1983. It was EPA's intent to provide a way to regulate dioxin as it would be defined as a hazardous waste. As proposed the rule would prohibit interim status facilities from managing dioxins until they are fully permitted. Three exemptions are: (1) wastewater treatment sludges that were generated in surface impoundments that contained dioxin, (2) tank and container facilities, and (3) wastepiles that were enclosed in some type of facility. This proposed rule would regulate wastes generated from specific processes that could contain dioxins. The term "generate" would also apply to wastes that were moved, picked up or moved about which would also be applicable to the dioxin situation in Missouri. This proposed rule would also have jurisdiction over the permitting requirements for the management of dioxin contaminated wastes. This proposed rule is open for comments until June 3, 1983.

Dick Smith, U.S. Environmental Protection Agency, then discussed the procedures that will be used in selecting a remedial action at a hazardous waste site that is on EPA's National Priority List. He also discussed requirements under the National Contingency Plan which spells out the requirements for feasibility studies.

There was then some discussion among the task force about meeting dates for the months of June, July and August. The meeting dates of June 16 and July 21 were set. There was also some discussion on the May 12 agenda.

Ron Kucera then announced that Congressman Volkmer's office had invited the department to testify before its Science and Technology Subcommittee in Washington. He planned to tell them that: (1) R & D monies in the EPA budget should not be cut at this time, and (2) there should be an extension of time on the Superfund.

There was then some discussion on what should be included in the interim report due June 1. It was decided that the program staff would prepare a draft report up to Chapter 4. The task force members are to bring any ideas or conclusions they would like to see in the interim report to the next meeting. The members are also to send any comments or suggestions they have on the proposed regulation to Dave Bedan before the May 12 meeting.

ORDER OF BUSINESS

The meeting on Thursday, May 12, 1983, was called to order at 9:20 a.m.

The minutes from the April 28, 1983 task force meeting were approved as submitted.

Beth Rice, Waste Management Program, Department of Natural Resources, stated that the first company on the agenda, Midland Ross Corporation, did not wish to make a presentation. She passed out a statement from Irving Williams that stated the reasons why they did not wish to make a presentation.

The next presentation was by George VanderVelde, Technical Director for Chemical Waste Management, and Darrell Schimeck, a project administrator for Superfund activities, also of Chemical Waste Management. Mr. Schimeck stated there were nine key elements or factors they evaluated in determining a successful project. They are:

1. Public health and safety during operations and in resulting solution
2. Technically feasible
3. Operationally sound
4. Provides a solution that is environmentally sound and defensible
5. Compliance with regulations
6. Timing
7. Cost
8. Public reaction/opinion/perception in Missouri
9. Public reaction/opinion/perception in other states.

Chemical Waste Management then evaluated four potential treatment or disposal options in terms of these nine factors, breaking each down in positives and negatives and then made a recommendation for each option. The first option, incineration of dioxin contaminated soil, was recommended as a good option. The second option, secure burial, was recommended as a poor option. The third option, treatment of the dioxin contaminated soil by either physically or chemically neutralizing the dioxin contaminants, was recommended as a good option. The fourth option, site capping/encapsulation, was recommended as a good option.

Chemical Waste Management made the following conclusions:

1. Due to the volume of soil, destruction of dioxin with the soil is cost prohibitive.
2. Since dioxin is a major concern, dioxin should be extracted from the soil in order to again reduce the volume.
3. The dioxin which is excavated or extracted should be destroyed chemically and/or incinerated.
4. Again due to the volume of low level dioxin contaminated soil, removal and destruction of the dioxin with the soil is cost prohibitive.
5. Site capping and encapsulation should be considered as an alternative solution for select low level contaminated sites.
6. Because of public reaction and sensitivity by other states to receiving dioxin, as much of the dioxin processing and disposal should be done within the State of Missouri as is possible.

Considering those conclusions Chemical Waste Management's recommendations for primary operation are as follows:

1. Excavation and recapping of high level dioxin sites.
2. Concurrent capping and encapsulation of the low level dioxin sites.
3. Extraction of the dioxin from the excavated soils.
4. Disposal via a secure burial of soil following the dioxin extraction.
5. Treatment/destruction of dioxin contaminated soil extract medium via the ultraviolet light process.
6. Ocean incineration of the treated soil extract medium.

Based upon the current level of information, Chemical Waste Management estimated the total cost to be between $22-$65 million and the total time of the project completion to be 14-24 months.

George VanderVelde then discussed a proposal to build a facility within the state that would involve chemical separation. The process would remove the dioxin from the soil, concentrate that dioxin into a liquid medium which could then be reduced in terms of dioxin that is present through the means of a UV process. The UV process would reduce the level of dioxin. The liquid material which contains the bulk of the dioxin would be incinerated and the very low level material left in the soil would then be buried in a secure landfill.

The next presentation was by Tom Cody, Vice-President of Critical Fluids Systems, Inc. Mr. Cody discussed Critical Fluids Systems' technology which is based on the use of condensed gases as extracting solvents. The technology has never been applied specifically to dioxin, but has been successful in extracting other chemicals and materials from the soil. Critical Fluids Systems proposes that a small-scale test program be done to determine the feasibility of utilizing critical fluid extraction technology. After the test program, a recommendation would be made on the feasibility of proceeding with subsequent phases leading to construction of a full-scale processing plant to be operated by a waste management company. The cost of the proposal would be as follows:

Set-Up (6 months)	$ 350,000
Run	500,000
Pre-Design Engineering Package (3 months)	50,000
Extraction Plant (process 3.5-7.0 tons/hour)	3,000,000

The next presentation was by Tony Schraub, Mechanical Engineer, and Leo Weitzman, Chief Scientist, from Acurex Waste Technologies, Inc. Mr. Schraub discussed their process which destroys dioxin by chemical transformation of the dioxin molecule and produces a safe polymer. The Acurex dioxin soil cleanup process would involve the following steps:

1. Move portable equipment to contaminated site
2. Preparing the soil (wetting it thoroughly so that dust is eliminated or reduced)
3. Scoop dioxin soil directly into soil washing machines
4. Wash soil with agitation in special Acurex solvent
5. Remove solvent from soil by vacuum extraction
6. Return safe soil to original location
7. Purify solvent and concentrate pollutant into small-volume sludge
8. Treat sludge with Acurex dioxin and PCB destruction process rendering harmless
9. Remove equipment and sludge, leaving clean site
10. Regreen site as appropriate.

Some of the benefits of the Acurex soil cleanup solution are: cleans dioxin or PCB from soil to specified level; destroys the dioxins; safe (nonflammable, etc.); process already demonstrated in Missouri; no transport of contaminated soil from site; controllable and verifiable; creates no secondary pollutants or migration; and returns the site to an environmentally safe and clean condition. The preliminary cost, assuming 10,000 cubic yard cleanup at a site which is relatively accessible, would be $200-$500 per cubic yard.

The next presentation was by John Schofield and Jurgen Exner of IT Enviroscience. Mr. Schofield discussed two solutions for destroying dioxin: (1) destruction by thermal oxidation or incineration and (2) destruction by a chemical means. Dioxin could be destroyed by a chemical process such as the ultraviolet process. This would be a potential solution for a site that is lightly contaminated with dioxin that is fairly close to the surface. The cost for such an in situ chemical process would be approximately $50 per ton. The other solution would be destruction of the material by incineration in a cement kiln. Cement kilns could handle thousands of tons per day. Two things would be required: (1) to prove to the public that incineration can destroy dioxin (this demonstration could be done by using the EPA mobile incinerator) and (2) carry out engineering feasibility of converting a cement kiln to a soil incinerator. This process would cost approximately $200 per ton.

The next presentation was by James L. Boyland, Director of Business Development for the Midwest Region for SCA Services. Mr. Boyland stated that SCA Services believes incineration is the best proven technology for destruction of dioxin and that a cement kiln would offer the best solution. They have not estimated any costs as of yet. Mr. Boyland also discussed a team that SCA Services had formed to look into the problem. Battelle Columbus Laboratories is on this team to assess, to evalute and to recommend technologies. Fru-Con Corporation is also on this team as specialists in the design and construction of any kinds of facilities that would be anticipated. SCA Services would be the prime contractor and operator for the project.

The next presentation was by Ed Hillier, Field Services Group of Rollins Environmental Services, Inc. and Don Matter, Field Services Manager. Mr. Hillier proposed that off-site incineration may be feasible for small amounts of dioxin, assuming you would want to move the material as fast as possible. Rollins Environmental recommends above ground storage of the material until new technlogies are developed and proved to be effective. The estimated cost for off site incineration for 500,000 cubic yards would be $234,000,000 which includes removal and transportation. The time period would be approximately 5600 days. The estimated cost for above ground storage for 500,000 cubic yards would be $26,600,000 which includes excavating, transportation, construction and waste placement. Don Matter discussed the option of incineration. He stated that the ash from incineration would still have to be made secure in a licensed permitted facility.

Ron Kucera, Department of Natural Resources, informed the task force of the results of his trip to Washington, D.C. and his testimony before the Science and Technology Committee that was requested by Congressman Volkmer. He indicated to the committee that Missouri would benefit by an extension of the Superfund Act and that Missouri would like to have some additional R & D monies for research needs.

Greg Peterson, CH2M Hill, the firm contracted to do the Minker/Stout feasibility study, provided additional information on temporary stabilization of the material at the Minker/Stout site until new technology is developed. The firm looked at approximately 20 alternatives, including a polyurethane spray foam. The cost for this, including monitoring wells, would be between $1-$2.5 million.

The task force then brought up the question to Dick Smith, U.S. Environmental Protection Agency, that if a site on the National Priority List did some type of interim action such as temporary cover, if that would cause the site to be removed from the list since there would no longer be an immediate risk?

Dave Bedan, Waste Management Program, Department of Natural Resources, then went over the different chapters in the draft of the interim report. The task force then discussed whether Chapter 5, The Theory of and Procedures for Health Risks Assessment, should be included in the interim report. It was decided that the title of Chapter 5 should be changed and should include what the Division of Health has been doing and what their interaction with CDC has been. It was also decided that Chapter 6 would be discussed in further detail at Friday's meeting and if time permitted, there would be discussion on proposed revisions to EPA's new regulation, otherwise this item would be put on the May 26 agenda. A suggestion was also made that there should be a statement in Chapter 6 making it perfectly clear that the recommendations were site specific and are not recommendations for other sites which have not yet been adequately addressed.

The meeting was adjourned at approximately 5:00 p.m.

Respectfully submitted,

Dianne Luebbert

ORDER OF BUSINESS

The meeting on Friday, May 13, 1983, was called to order at 8:10 a.m.

The task force discussed several recommendations and suggestions for the interim report due on June 1, 1983. These suggestions and recommendations were as follows:

1. The report should address only the Minker/Stout and Times Beach sites. The remaining dioxin sites should be listed in the appendix with a statement that they are being included for information only.
2. On page 3 of the "Historical Summary" (3rd paragraph), there should be a note to refer to the body of the report for further clarification of half-life.
3. Would like to see additional sampling at various points in Times Beach to determine levels of contamination and to determine the extent of the problem.
4. Would like to see surface water and ground water sampling by use of bio-indicators and activated carbons and resins to determine if contamination exists and then to determine if that contamination is a result of leaching or sediment transport.
5. The report should outline the effects of the buyout at Times Beach. It should state that actions already taken have alleviated the problem and have removed the immediate risk.

6. The report needs to state that interim stabilization of the soil at the Minker/Stout site needs to be done. For instance attach a pipe to the drain pipe that runs under the road and run that pipe down off the hill. The report then should state that remedial work needs to be done at both the Minker/Stout and Times Beach sites.

7. Should assign priorities in the report. Minker/Stout should be given first priority and state the reasons why it should be first. Minker/Stout is an unstable site, whereas Times Beach is more stable.

8. Specific conclusions and recommendations for Times Beach:

   a. Buyout should be expedited. Should include removal of people. Access should be limited.

   b. With reduced exposure there is no need for further immediate action. Testing will continue.

   c. Health risks:

      (1) Has been reduced because of removal of exposure.

      (2) Study of health effects to residents should be broadened and continued.

      (3) Will reassess health effects.

   d. Initial remedial action - Taking measures to limit access. When state obtains title, then can totally restrict access.

   e. Planning for final remedial action should be continued based upon further study.

9. Specific conclusions and recommendations for Minker/Stout:

   a. Buyout should be expedited.

   b. Immediate remedial action is called for. Short term action is in order such as culvert, sod, and grass to stop erosion.

   c. Planning for final remedial action should be continued. Should have statement about geology at the site. Should proceed with all deliberate speed.

10. Should select three or four of the options for remedial action the task force heard about and place emphasis on them.

11. State or federal government should consider a centralized location for a treatment facility or storage area.

12. Small sites should not use portable equipment but should take material to state or federally owned area.

13. Monitoring should be done at Minker/Stout site after drain pipe installed and other initial action completed.

14. Soil from one of the sites should be sent to the Pine Bluff, Arkansas incinerator for a test burn.

The task force then discussed the different options for remedial action. A summary of the discussion for each option is given below:

Stabilization In Place - A grout curtain is not a recommended action for the Minker/Stout or Times Beach sites, but may be used for other sites. Discuss further under further studies. Also recommended long-time research into organic polymers as fixatives.

On-Site Storage - Do not recommend on-site storage at each and every site. Portable equipment would be burdensome to move, would cost a large amount of money, would require individual permits, and would have to set up such things as generators, water, power, etc. Recommend one centrally located facility and bring all the material to that facility to store, treat, etc. Recommend a preliminary study that would look into possible sites where a facility and storage space could be constructed. In most cases on site storage would appear not to be feasible, but there may be some special situations where it could be used.

Transport to Secure Landfill - Do not recommend as an option to pursue unless all other high technology fails.

Biodegradation - Recommend further research.

Incineration - Recommend a pilot burn at Pine Bluff to see if ash residue will be acceptable for non-hazardous disposal. Will have to determine if the dioxin is destroyed or if it is sent into the atmosphere. Request priority treatment to be placed on test list. Request research permit so this test can be done. Suggested someone might be able to visit Pine Bluff.

Extraction - Recommended further study in the field of extraction. Make a distinction that this is not an end solution.

In-Place Treatment - Recommended further research. This is not an immediate available solution. Photolysis process is not an end solution to problem. Recommended further research on ultraviolet radiation, gamma radiation, and lasers.

Temporary Storage or Stabilization Until New Technology Develops - Do not recommend as an option.

A summary list of those recommendations for further research are: organic polymers, incineration to a certain extent, extraction, biodegradation, in-place treatment such as ultraviolet radiation, gamma radiation, lasers, etc. and bioavailability.

Dick Smith, U.S. Environmental Protection Agency, also discussed a study that will begin in the near future by the Division of Geology and Land Survey on Romaine Creek. They will be looking at the sediment transport issue and will be determining general ground water movements in the Minker/Stout area. DGLS will be installing stream gauges and will be injecting dye at various points in the stream basins. They will also be surveying wells in the area.

Dick Smith also addressed a question from the previous day about whether a site that is on the National Priority List and has completed interim action that has reduced a risk, whether that site would be taken off the list because of the interim action. Mr. Smith stated that once a site has received a hazard ranking score sufficient to put it on the National Priority List, that site is not re-scored at any point. It remains on the list until final action is completed.

It was also decided that the next meeting would remain on May 26 instead of May 23. There had been discussion at the previous meeting to change the date to May 23.

James Shaddy suggested that since the task force had mentioned several topics that need further study or further research, that they could possibly solicit research needs from the University of Missouri - Columbia coordinator.

The meeting was adjourned at 2:40 p.m.

Respectfully submitted,

Dianne Luebbert

APPENDIX IV

PROCEDURES FOR SELECTING A REMEDIAL ACTION

Background

Section 104(a)(1) of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) authorizes the President to provide remedial actions which are necessary to protect the public health, welfare, or the environment at waste sites. The National Contingency Plan (NCP) provides the regulations necessary to implement CERCLA and outlines the basic procedures for selecting a final remedial action. Pursuant to a delegation of authority, the EPA Assistant Administrator for Solid Waste and Emergency Response is empowered to approve the selection of remedies for hazardous waste sites. The statutory and regulatory requirements for documenting the remedy selection are discussed in the following sections.

CERCLA Requirements

The selection of the final remedial action occurs after the completion of the feasibility study and is subject to fundamental statutory requirements contained in CERCLA. The key declarations that are necessary for every remedial action recommendation are:

1. EPA has consulted with the State before determining the appropriate remedial action [Section 104(c)(2)];

2. The action being taken is (a) a cost-effective solution and (b) appropriate when balanced against the need to use Trust Fund money at other sites [Section 104(c)(4)];

3. The proposed remedy effectively mitigates and minimizes damage to and provides adequate protection of public health, welfare and the environment; and

4. When the selected action involves off-site disposal, these additional declarations are, also, satisfied [Section 101(24)]:

   a. The action is the most cost-effective when compared to other possible remedial actions;
   b. The action will create new capacity to manage, in compliance with the Solid Waste Disposal Act, hazardous substances in addition to those located at the site in question; and
   c. The action is necessary to protect the public health, welfare, or the environment from a present or potential risk which may be created by further exposure to the continued presence of such substances.

NCP Requirements

The NCP regulations outline certain procedures for identifying, evaluating and selecting a remedial action which provides a permanent remedy to prevent or mitigate the migration of a release of hazardous substances into the environment. These regulatory procedures are based upon the statutory requirements contained in CERCLA and are summarized below.

1. Development of Alternatives - A limited number of alternatives is developed for either (1) source control actions where wastes remain at or near the area where they were originally located; (2) off-site remedial actions when wastes have migrated off-site; or (3) both types of actions.

2. Initial Screening of Alternatives - The alternatives developed are subject to an initial screening to narrow the list of potential remedial actions for further detailed analysis. The alternatives are evaluated according to these factors: (1) costs; (2) environmental effects and overall effectiveness; and (3) acceptable engineering practices.

3. Detailed Analysis of Alternatives - A more detailed evaluation is conducted of the limited number of alternatives that remain after the initial screening.

4. Selection of Remedial Alternative - The lead agency (either EPA or the State) selects the remedial alternative which the agency determines is cost effective (i.e., the lowest cost alternative that is technologically feasible and reliable and which effectively mitigates and minimizes damage to and provides adequate protection of public health, welfare or the environment).

Development of the Record of Decision (ROD)

The mechanism that has been developed to document the remedial action selected is the ROD. This decision document is prepared by EPA with assistance from the State whether EPA is the lead agency or not. The ROD, also, insures that the selected remedy is based upon appropriate data and is in accordance with the CERCLA requirements and Superfund policy.

The following activities provide an outline of the review and approval process necessary to select and implement a remedial action. Deviations from this outline of activities may occur depending on the nature and complexity of the site. Also, the length of time necessary to accomplish these tasks will depend on these same factors.

1. The draft feasibility study is submitted for review.

2. The EPA Regional Office reviews the draft feasibility study for compliance with the NCP.

3. The Regional Office confers with the State on the results of the feasibility study to ensure that the State concerns are adequately addressed in recommending appropriate remedial actions.

4. The Regional Office prepares a draft ROD to obtain approval to initiate remedial actions.

5. The State assists the Regional Office in developing information to support the ROD recommendation and submits a letter indicating the State's support of the selected remedial action.

6. The Regional Office provides a three (3) week public comment period regarding the draft feasibility study and draft ROD followed by a public meeting to receive citizen comments.

7. The public comments are incorporated into the draft feasibility study and draft ROD and the Regional Office prepares a responsiveness summary outlining the public comments and providing EPA's responses to them.

8. The draft ROD and supporting documentation are submitted to EPA Headquarters for review.

9. The Regional Office in cooperation with the State then develops the final ROD after incorporation of the Headquarters' comments.

10. The Regional Office submits the final ROD to Headquarters for approval.

11. The Assistant Administrator for Solid Waste and Emergency Response approves the ROD after balancing the need for the remedial action at this site against the amount of money available in the Fund to respond to other sites.

12. Following approval of the ROD, funds for the remedial action will be obligated and the activity will be implemented through a Cooperative Agreement or a new or amended State Superfund Contract which provides all required State assurances, including assurance of the availability of an acceptable hazardous waste disposal facility.

APPENDIX V

TESTIMONY OF
MISSOURI DEPARTMENT OF NATURAL RESOURCES
BEFORE COMMITTEE ON SCIENCE AND TECHNOLOGY
(U.S. CONGRESS)

May 4, 1983

Mr. Chairman, Members of the Committee.

My name is Ron Kucera. I would like to extend my thanks to the committee for the opportunity to appear here today to discuss the subject of alternatives to the landfilling of hazardous waste. I serve as deputy director for the Missouri Department of Natural Resources. Our Department has responsibility for parks management, historic preservation, geologic resources, energy, and environmental quality. Without a doubt the most difficult issue facing our agency has been the management of hazardous waste including wastes currently generated as well as those which did not receive proper or adequate disposal in the past.

I am proud to say that it is the policy of the State of Missouri, enunciated in statute, to discourage the landfilling of hazardous waste. In 1980 the Missouri General Assembly passed amendments to the State's hazardous waste law enacting more stringent standards for the permitting of landfills, placing a tax on the generation of hazardous waste, and requiring the use of practical alternatives to landfilling. The injection or landfilling of bulk liquid hazardous waste is entirely prohibited. Missouri is a leader among the states in reducing the dependence on landfilling for the management of hazardous waste. Currently, less than 5% of wastes generated in Missouri are destined for disposal by landfilling. We are now vigorously pursuing further amendments to our waste law which will place a very substantial tonnage tax on all hazardous waste that is disposed of through landfilling. We are confident that this new law will provide strong additional incentives to Missouri industries to invest in process changes, recycling, treatment, and incineration. The revenues from this new tax will be targeted to the correction of problems caused by poor waste management practices of the past.

As the members of this committee are most certainly aware, the public policy concerns over the use of landfills are not restricted to the matter of current and future waste generation. The clean-up of old inadequate or leaking waste sites often yields large volumes of waste that must be managed by legally approved hazardous waste facilities. If, as is frequently the case, large quantities of contaminated soil are involved, landfilling usually is thought to be the least-cost option when compared to treatment or incineration. Though we do not yet have good cost estimates, this relationship appears to hold for the remedial action alternatives available for many of Missouri's dioxin sites.

I would like to take just a minute to acquaint the committee with the numbing reality of the dioxin problem that we are facing in Missouri. It is a dilemma of almost unfathomable proportions, and there is no tonic cure, no easy solution. As of this week our Department's investigators working cooperatively with the staff of the Kansas City regional EPA office had confirmed through quality-assured sampling and analysis the existence of 30 separate dioxin sites in Missouri. Our investigators continue to find additional leads, and if the current trends persist, we will no doubt confirm more contaminated sites.

It is estimated that the total volume of contaminated soil with greater than one part per billion 2,3,7,8 tetrachlorodibenzo-p-dioxin could exceed 400,000 cubic yards or 500,000 tons. The oft-suggested solution of high temperature incineration could easily cost more than $2,000 per ton or more than $1 billion for all the dioxin contaminated material known to date in Missouri. Another alternative, solvent extraction with subsequent incineration or ultraviolet photolytic degradation would most likely involve even higher costs. Furthermore, investigations may reveal similar though perhaps smaller dioxin problems in Arkansas, California, Illinois, Kansas, Michigan, New Jersey, New York, Ohio, Oregon, and Pennsylvania. Obviously, the large potential costs for incineration and solvent extraction technologies could exceed the capability of the federal Superfund.

If we must decide between the less costly options of landfilling and some hybrid of on-site stabilization and land treatment, then it is abundantly clear that we must know more about the fate of dioxin in soil as a function of time. Unfortunately, we have found that there are crucial information deficiencies. The basic research that would allow us to make confident predictions about the behavior and half-life of dioxin in Missouri soils has not yet been initiated. Fundamental questions about the naturally occurring reduction of dioxin concentrations in soil through photolysis, biotic activity, volatilization, and solution have not been answered with adequate precision. Amazingly, after all the years of debate, we do not yet have a good handle on the half-life of dioxin in soil, nor do we know which degradation process predominates. Hopefully, through research we may learn that there are effective methods for enhancing and accelerating natural dioxin degradation in on-site applications. It should be noted that natural degradation processes might be severely reduced in the environment of a landfill thereby guaranteeing lengthy persistence of the dioxin.

It is vital to our efforts in Missouri that the research and development program within EPA provide accelerated funding to dioxin-related research activities. This is definitely not the appropriate time to diminish the EPA budgetary commitment to research. We cannot afford to base multimillion dollar remedial action decisions on nickel research.

May 26, 1983

SUMMARY OF SITES WHERE THE PRESENCE OF DIOXIN HAS BEEN CONFIRMED

1. Minker Residence Site:

   This site is located near Imperial. The known concentrations of dioxin at the site range from .3 to 300 ppb. The contaminated soil at this site originated at the Bubbling Springs Stables. MDNR geologists indicate that this site is in a very poor geological setting. EPA personnel have conducted intense sampling at the site. Contaminated soil from this site has eroded to three (3) adjacent properties. This site along with Romaine Creek and the Stout Residence Site is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a Feasibility Study for the sites.

2. Romaine Creek:

   Drainage to Romaine Creek comes from Minker and Bubbling Springs areas. The known concentrations of dioxin in thee creek sediment range from .3 to 272 ppb. EPA is conducting future sampling and investigation. This site along with Minker and the Stout Residence Site is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a Feasibility Study for the sites.

3. Stout Residence Site:

   This site is located near Imperial. The known concentrations of dioxin at this site range from 2.1 to 21 ppb. The contaminated soil at this site originated at the Bubbling Springs Stables. EPA is presently investigating this site and conducting additional sampling. This site along with Romaine Creek and the Minker Residence Site is included on the National Priorities List. A State Superfund contract has been signed with the State for these three sites. The contract covers relocation and a Feasibility Study for the sites.

4. Spring River:

   This river flows along the property line of the Syntex plants and runs westward. EPA, Missouri Department of Conservation (DOC) Division of Health, and MDNR have combined efforts to investigate the dioxin problem in the river. Sediment samples analysis indicate dioxin levels in the river sediment range from .004 to .087 ppb. Sampling of the fish in the river indicates dioxin levels in the fish flesh range from .019 to .04 ppb. The DOC has issued a warning to the people of the area to limit their fish consumption. A continued sampling effort is being conducted to determine if seasonal trends develope.

5. Denney Farm Site:

This site is located near Verona. This site originally contained levels ranging from 50,000 to 2,000,000 ppb. These high levels are from drum samples buried at the site. EPA and Syntex are working to complete the clean-up of the site. This site has been fenced and buried wastes have been dug up and secured above ground. Syntex has accepted responsibility for this site. The remedial work has been conducted by Syntex under the terms of a Consent Decree.

6. Shenandoah Stables Site:

This site is located near Moscow Mills. The known levels of dioxin at this site range from 1.4 to 1750 ppb. This is another site that was investigated by both EPA and CDC in 1974. The higher concentrations at the site are in the slough area adjacent to the arena. Some of the contaminated material was used as fill material along Highway 61 near the stables. Recent investigations have been unable to confirm dioxin in the fill material. The site is included on the National Priorities List. An Administrative Order to close the arena has been sent to the owner for signature.

7. Bliss Farm Road Site:

This site is located near St. James. The known levels of dioxin at this site range from .1 to 382 ppb. These concentrations are much lower than the concentrations of the samples taken by CDC in 1974.

8. Bubbling Springs Ranch Site:

This site is located near Fenton. The known concentrations of dioxin at this site range from 1.4 to 95 ppb. The site was originally investigated by both EPA and CDC in 1974. Contaminated soils have been excavated over the years and used as fill material at the Minker Stout, Sullins, and Cashel properties. An Administrative Order to close the arena has been sent to the owner for signature.

9. Neosho Digester, Trench, Tank, Spill Area, and Wastewater School:

This site is located near Neosho. The known levels of dioxin at the tank and spill area range from 62 to 1900 ppb. The known levels of dioxin at the digester and trench range from .49 to 60 ppb. EPA, the City of Neosho, and the Receiver of the defunct Wastewater School are negotiating the permanent capping and clean-up of the site. This capping will protect the public from contact until EPA determines an allowable amount of dioxin in the soil. Hopefully, action at this site will be completed by January 1, 1983.

10. Timberline Stables:

This site is located near New Bloomfield. The known levels of dioxin at this site range from .7 to 53 ppb. This is another site that was investigated by both EPA and CDC in 1974. Some of the contaminated soil was supposed to have been disposed of at the Jefferson City Landfill on Highway 94. Investigations thus far have not located any dioxin at the landfill. An Administrative Order to close the arena has been sent to the owner for signature.

11. Erwin Farm Site:

    This site is located near Verona. The known levels of dioxin at the site range from .006 to .83 ppb. The higher concentration is from a composite sample of drums being stored at the site. EPA has been working with Mr. Erwin & Syntex to accomplish the clean-up of the site.

12. Rusha Farm Site:

    This site is located near Aurora. The known levels of dioxin at the site range from .4 to 8 ppb. The higher concentration is from a sample of one drum of filter cake material being stored at the site.

13. Syntex Facility - Verona:

    This site is located near Verona. It consists of several disposal areas on the Syntex Plant property. EPA has been working with Syntex to clean up the site. Syntex has accepted responsibility for this site and is conducting a field investigation under the terms of an Administrative Order to determine the extent of contamination. The level of dioxin in wastes stored on site is about 500 ppb.

14. Bill Ray Farm Site:

    This site is located near Verona. It consisted of eighteen (18) drums removed from the NEPACCO (Syntex) property. Investigations indicate fifteen (15) drums are empty, one (1) drum contained no detectable amounts of dioxin, and two (2) drums with detectable amounts of dioxin. EPA has negotiated with Syntex to return the two (2) drums to the Syntex property.

15. Times Beach Site:

    This site consists of the twenty-eight (28) miles of roads in Times Beach and the city park area. The known levels of dioxin range up to 300 ppb. EPA and MDNR are investigating solutions to the problem. CDC has recommended evacuation of the town. The City is included on the National Priorities List.

16. Ruth Sullins Property:

    This site is located near Imperial. The known concentrations of dioxin at the site range up to 100 ppb. The contaminated soil at this site originated at the Bubbling Springs Stables and covers the corner of her three quarter acre lot. EPA expects to combine this site with the Minker/Stout/Romaine Creek site.

17. Southern Cross Lumber Company Site:

    This site is located in Hazelwood. The known concentrations of dioxin at the site range up to 27.3 ppb. The site was sprayed by Bliss from 1970-76. The site is now covered with gravel.

18. Saddle and Spur Club Site:

This site is located in northern Jefferson County. The known concentrations of dioxin range up to 15 ppb. Investigations indicate the area was oiled by Bliss late '71 or early '72. The stable property is approximately five (5) acres. The arena floor has been covered with sand. An Administrative Order to close the arena has been sent to the owner for signature.

19. Hamill Transfer Company Site:

This site is located in south St. Louis. The known concentrations of dioxin at the site range up to 15.6 ppb. The site was oiled by Bliss on May 27, 1972, using 8,000 gallons of waste oil. Since that time, the site has been "sealed" with a five (5) inch tar and gravel mixture.

20. Overnite Transfer Inc., Site:

This site is located in north St. Louis. The known concentrations of dioxin at the site range up to 9.2 ppb. The site was oiled by Bliss annually between 1962 and 1976. The site is now a five (5) acre graveled parking lot.

21. Jones Truck Lines Site:

This site is located in north St. Louis, The known concentrations of dioxin at the site range up to 22 ppb. The site was oiled by Bliss in the early '70's. Since that time, the site has been paved with asphalt and is now being used as a 4-5 acre parking lot.

22. Methodist Church Site:

This site is located near Ellisville. The known concentrations of dioxin range up to 3.5 ppb. The site was oiled by Bliss in the early 70's. Since that time the site has been paved with asphalt and is now being used as parking for the church.

23. Cashel Residence Site:

This site is located across Romaine Creek Road from Bubbling Springs Stables. The known concentrations of dioxin range between 10 and 100 ppb. The contaminated soil at this site originated at the Bubbling Springs Stables. EPA expects to combine this site with the Minker/Stout/Romaine Creek site.

24. Wall Property and Piazza Road Site:

This site is located near St. James. The known concentrations of dioxin range between 5 and 100 ppb. This site is adjacent to the Bliss Farm Road Site. Piazza Road was oiled by Bliss at the same time Bliss oiled his own road.

25. Russell Bliss Oil Company (Frontenac) Site:

This site is located in Frontenac. The known concentrations of dioxin range up to 100 ppb. This site was used by Bliss to store and mix waste oil until 1977.

26. Quail Run Mobile Home Park:

This site is located near Gray Summit. The known concentrations of dioxin range up to 1100 ppb. EPA's investigation indicates that Bliss oiled the roads at the Mobile Home Park.

27. Sontag Road Site:

This site is located in Castlewood. The known concentrations of dioxin at the site range from 1 to 60 ppb. This site was oiled by Bliss to control dust. This road has since been paved.

28. Syntex Facility - Springfield:

This site is located in Springfield. The known concentrations of dioxin range up to 8 ppb. This site consists of a holding lagoon which is being closed by Syntex under RCRA. EPA is working with Syntex to accomplish the clean up of the site.

29. Mid-America Arena Site:

This site is located near Ellisville. The known concentrations of dioxin range up to 78 ppb. This arena is part of the "Ellisville Area Site" which appears on the National Priority List. A Superfund Cooperative Agreement has been signed for the clean up of this site.

30. Sandcut Road Site:

This site is located near Cedar Hill. The known concentrations of dioxin range up to 24 ppb. A former driver for Bliss Oil lived in a trailer along this road and routinely "oiled" the road to control dust.

31. Baxter Garden Center:

This site is located off Wild Horse Creek Road in Chesterfield. The known concentrations of dioxin range up to 82 ppb. This site was oiled by Bliss in 1971. Even though this site is a commercial nursery, there is little, if any, public access to the contaminated area.

APPENDIX VII

SUMMARY OF INFORMATION PRESENTED TO THE TASK FORCE BY CH_2M-HILL*

Remedial Action Alternatives Being Considered

Over 50 possible treatment processes and over 500 sources of information were considered in the initial screening of remedial alternatives. The treatment processes shown on Figure 5-2 were screened on the basis of 1) state of development, 2) health and safety risks, 3) process complexity and constructability, 4) reliability, and 5) cost to arrive at six alternatives for further detailed analysis.

The remedial alternatives shown on Figure 5-3 are currently under evaluation for the Minker/Stout site. Five of these alternatives are technically feasible, reliable, and can effectively mitigate the risk to public health, welfare, and the environment with the use of today's technology, while the sixth depends on emerging technology. Alternatives A through C rely on the principal of containment to reduce dioxin exposure which, due to the demonstrated insoluble nature of dioxin in these soils, center around immobilizing the contaminated soil particles. Alternatives D through F rely on the principal of treatment to reduce dioxin level, in addition to containment of the treatment residue.

At this time, no sites have been identified for siting a hazardous waste management facility; therefore, EPA has directed that, for purposes of this study, the Minker site be the assumed location. The socioeconomic, political, and demographic impacts on the community resulting from the siting of such a facility are well beyond the scope of the feasibility study and will not be considered at this time.

Other remedial alternatives are possible and may be considered for other sites, or as a part of an overall Missouri Dioxin Feasibility Study.

Alternative A

This alternative would secure the soil in-place, prevent public site access, and establish a hazardous waste landfill at each fill area. This would likely involve insitu soil fixation and securing of the site with a subsurface perimeter grout curtain, an impermeable cap over the contaminated area, and diversion of surface runoff. Permanent resident relocation and house demolition would be necessary at the sites, and for additional households inside a buffer zone. A long-term site monitoring and maintenance program would be implemented to monitor the groundwater and surrounding environment.

Alternative B

This alternative includes removing the contaminated soil and consolidating into one area on the Minker site. Due to the very shallow soil depth, unsuitable site hydrogeology, and the need for a positve liner and leachate collection system, an above-grade concrete vault would contain the contaminated soil. Permanent resident relocation and house deomolition would be necessary at the sites, and for additional households inside a buffer zone. A long-term site monitoring and maintenance program is also required.

---

*CH_2M-Hill is a consulting engineering firm contracted by EPA to do the feasibility study for remedial action at the Minker/Stout site.

Alternative C

This alternative involves removing and transporting the contaminated soil to a secure hazardous waste landfill for disposal. Two potentially acceptable landfill sites have been located within a 600-mile radius of Minker/Stout. Per the April 3, 1983, Federal Register, EPA is currently considering the addition of dioxin wastes to RCRA regulations. If this proposed rule is promulgated, the design and operation of each landfill disposal facility will need to be thoroughly evaluated before dioxin can be added to their permit.

The removed soil volume and up to 2 feet of additional fill would be added to restore the site drainage and to cover any fugitive trace of contaminated soil. The site would be relandscaped and the houses rehabilitated, thus enabling the complete restoration of the area.

Alternative D

This alternative involves the direct thermal destruction of dioxin-bound soil. The contaminated soil would be removed to a concrete vault, where it would remain while the incineration process is pilot tested and developed for this particular contaminated soil. A significant permitting effort may be necessary for the siting of a full-scale facility. Following the permitting process and the construction of the facility, the soil would be transported to a size reduction and handling process, and then to an incinerator. The incinerator particulate and soil residue would be transported to a secure landfill site, unless extensive testing is able to prove them free of TCDD contamination.

The removed soil volume and up to 2 feet of additional fill would be added to restore the site drainage and to cover any trace of contaminated soil. Locating the storage vault and incinerator offsite would enable the area to be relandscaped and the houses rehabilitated, thus enabling the restoration of the area.

Alternative E

This alternative involves extracting the dioxin from the soil with a solvent, concentrating the solvent, and then destroying the dioxin in the solvent. The contamiated soil would be removed to a concrete vault, where it would remain while the solvent extracted process is pilot tested and developed for this particular contaminated soil. A significant permitting effort may also be necessary for the siting of a full-scale facility. Following the permitting process and the construction of this process, the soil would be transported to a size reduction and handling process, and then to the solvent extraction process. The resulting contaminated solvent would be concentrated, with the concentrate undergoing degradation and incineration. The incinerator particulate and the soil residue would be sent to a secure landfill site, unless extensive testing is able to prove them TCDD-free.

The removed soil volume and up to 2 feet of additional fill would be added to restore the site drainage and to cover any trace of contaminated soil. Locating the storage vault, solvent extraction process, and the incinerator offsite would enable the area to be relandscaped and the houses rehabilitated, thus enabling the restoration of the area.

Alternative F

This alternative allows for the development of emerging technologies. The contaminated soil would be removed and stored until such time that emerging technologies such as supercritical water reactors, wet air oxidation, and biological degradation are pilot tested and evaluated for their ability to be competitive with existing technology. Today, these emerging technologies are not considered to be commercially developed for this type of hazardous waste and each has several major technical hurdles to overcome. There is a risk that the emerging technologies may never become cost-effective for this waste and, therefore, a contingency plan will be necessary, should the research and development program not proceed as quickly as planned or is unable to demonstrate on acceptable alternate technology.

The prediction of the timetable for Minker/Stout remedial action is difficult due to unpredictable variables such as site hydrogeologic problems, technical difficulties which may arise during process development, permitting delays, design problems, bidding periods, construction delays, extended public comment periods, and possible legal intricacies. Based on the key assumption that none of these variables will pose an abnormal project delay, the following minimum schedules have been discussed for the completion of the remedial alternatives and the restoration of the site. Onsite remedial activities are only a small portion of the total required schedule.

Alternative	Minimum Total Schedule	Remedial Action
A	3 years	1 year
B	3 years	1 year
C	2-1/2 years	1/2 year
D	8 years	3 years
E	11 years	3 years

Remedial Action Costs

The following comparative cost estimate (+50, -30 percent accuracy) was established for 5,000-8,000 cubic yards of contaminated soil from the Minker/Stout site. This volume estimate is in the process of being revised to reflect the latest increases in the Stout area of contamination.

The estimated costs are intended to be inclusive of all of the direct and indirect costs associated with a particular remedial action for Minker/Stout. The enclosed figure, "Comparison of Costs Included in Remedial Alternatives," indicates a typical scope of what is included in the cost estimate. Many of the costs are highly site-specific for the difficult conditions at the Minker/Stout site and may not apply to any other site.

	Estimated Cost ($ Millions)	
Alternative	5,000 yd^3	8,000 yd^3
A	29	30
B	9	11
C	4 1/2	8
D	29	38
E	57	77

We are in the process of refining the basis of these estimated costs and to incorporate the data received since our March 30 presentation. At this time, it appears that the requirements for size reduction and solvent incineration may be significantly reduced from these initial estimates. Because of this, the capital cost of Alternatives D and E may be reduced by as much as 20 percent over the initial estimates.

The estimated costs are prepared for guidance in project evaluation and implementation from the information available at the time. The final costs of the remedial action will depend on actual labor and material costs, competitive market conditions, final scope, levels of personnel protection and decontamination, implementation schedule, and other variable factors. As a result, the final project estimate and actual implementation cost will vary from the estimates presented.

Process/Technology	Description	Fate of Dioxin	Byproducts	Commercial Status	References
FIXATION					
1. Organic polymer	Soil containing TCDD is mixed with an organic polymer which hardens.	TCDD and soil are bound together	None	Used routinely on commercial scale for soil; no TCDD experience	
2. Inorganic with cement, fly ash, or ceramic	Soil containing TCDD is combined with portland cement or fly ash. Moisture is added as required to cause the mixture to set.	TCDD and soil are bound together	None	Used routinely on commercial scale for soil; no TCDD experience	
3. Carbon	Soil containing TCDD is mixed with activated carbon. Free or uncomplexed TCDD is adsorbed on the carbon	TCDD in soil and TCDD on carbon are mixed together	None	Conceptual	
4. Encapsulation	Soil containing TCDD is enclosed in a barrier of low permeability such as high density polyethylene	TCDD and soil are enclosed	None	Commonly used for encapsulation of hazardous waste	
SECURE IN PLACE	Securing the site and capping with bentonite clay	TCDD remains on-site in secured location	None	Demonstrated on industrial scale	
IN-SITU DEGRADATION					
1. Ultraviolet degradation	A suitable hydrogen donor (preferably non-toxic and non-volatile) is applied to the soil followed by irradiation with sunlight or high-pressure mercury lamps.	Soil remains in place; TCDD is degraded; TCDD may be spread by the solvent.	Soil contains TCDD decomposition products	Tried at Seveso with limited success	
2. Chemical degradation	A chloroiodide micellar solution is applied to the soil and the ether bonds of the TCDD are cleaved.	Soil remains in place; TCDD is degraded	Soil contains TCDD decomposition products	TCDD in a 100g sample of Seveso soil has been 52% degraded in a laboratory test	
EXTRACTION					
1. Solvent	Soil is processed to enable extraction with solvent and then TCDD is extracted from soil with solvent in either a batch or continuous operation.	TCDD in solvent	Soil containing solvent	Bench-scale experience only with soil but commercial experience with sludge from distillation bottoms at Verona	
2. Steam stripping	TCDD is volatilized from soil by contacting with steam.	TCDD with water as insoluble phase	Possible TCDD thermal decomposition products	Conceptual	
CONCENTRATION					
1. Adsorption, carbon	Solvent containing TCDD is passed through activated carbon	TCDD is adsorbed on carbon	TCDD free solvent	Pilot testing on herbicide orange	
2. Adsorption, resin	Solvent containing TCDD is passed through resin.	TCDD is absorbed on resin	TCDD free solvent	Laboratory tested to remove pesticides from wastewater; conceptual only for TCDD	
3. Distillation	Solvent is distilled and TCDD is concentrated in the distillation bottoms.	TCDD in distillation bottoms	TCDD free solvent	Commercially used in pesticide manufacturing process; also done at Verona	
4. Membrane processing	Selective passage of solvent through a membrane, as in reverse osmosis or ultrafiltration.	TCDD concentrated in solvent	TCDD free solvent	Conceptual

DEGRADATION					
1. Radiation treatment					
a. UV degradation	TCDD is irradiated with sunlight or high pressure mercury lamps in the presence of a suitable hydrogen donor after solvent extraction from soil. TCDD in solvent is irradiated with gamma radiation.	TCDD degradation	Solvent with TCDD decomposition products	Commercially done at Verona	
b. Gamma	TCDD in solvent is irradiated with gamma radiation.	TCDD degradation	Solvent with TCDD decomposition products	Laboratory tests on TCDD in solvent	
2. Chemical Treatment					
a. Catalytic dechlorination	TCDD in solvent is dechlorinated with Nickel Borohydride catalyst.	TCDD degradation	Solvent with TCDD decomposition products	Conceptual	
b. Chlorination	TCDD in solvent is extensively chlorinated between 600 and 800° C and 150 psig.	TCDD degradation	Solvent with TCDD decomposition products of CCl_4, HCL, and $COCl_2$	Piloted on herbicide orange	
c. Ruthenium tetroxide	TCDD in solvent is oxidized with ruthenium tetroxide	TCDD degradation	Solvent with TCDD decomposition products	Laboratory tests only	
d. Chloroiodides	TCDD is reacted with chloroiodides in a micellar solution	TCDD degradation	Solvent with TCDD decomposition products	Laboratory tests only	
e. Ozone/UV	TCDD in solvent is reacted with ozone and irradiated with ultraviolet light.	TCDD degradation	Solvent with TCDD decomposition products	Laboratory tests only	
f. Chemical dechlorination	TCDD is reacted with an aromatic liquid and alkaline reactants.	TCDD degradation	Solvent with TCDD decomposition products	Laboratory tests only	
3. Thermal Treatment					
a. Wet air oxidation	TCDD is catalytically oxidized at 200° C in a wet air oxidation process.	TCDD degradation	TCDD decomposition products	Laboratory tests with TCDD	
b. Conventional hazardous waste incineration	TCDD in soil or solvent is combusted in a hazardous waste incinerator.	TCDD degradation	TCDD decomposition products	Commerical incineration available for PCB's, other hazardous wastes; TCDD incinerated with herbicide orange on the M/T Vulcanus	
c. Molten salt combustion	TCDD in solvent is injected below the surface of a molten salt bath in a reactor at 1500° F to 1800° F	TCDD degradation	TCDD decomposition products; spent molten salt melt	Laboratory tests with chlorinated hydrocarbons	
d. Microwave-plasma destruction	TCDD in soil or solvent is mixed with partially ionized gas produced by microwave-induced electron reactions.	TCDD degradation	TCDD decomposition products	Pilot-scale tested on PCB's and other toxic products materials	
e. Pyrolysis	TCDD in soil or solvent is decomposed by heat alone.	TCDD degradation	TCDD decomposition products	Conceptual

COMPARISON OF COSTS INCLUDED IN REMEDIAL ALTERNATIVES

PRELIMINARY
4-12-85

Mr. **Levitas**. Congressman Gephardt, would you like to make your statement at this time or would you like to wait?

Mr. **Gephardt**. I would like to wait and introduce the next group, which is from my district.

Mr. **Levitas**. Thank you.

Mrs. Leistner, you were sort of in the middle of this as an individual and also as a public official. From this point of view, I got the impression that after the Federal response was made and decisions were made, it appeared to me to be a lot of confusion and hassling and haggling within the Missouri State Legislature about whether they were going to put up the matching funds necessary, or how they were going to proceed, and all sorts of technical problems. Were you involved in this at all? Is my perception correct? Or did everything sort of run smoothly?

Mrs. **Leistner**. We have not been in on any of the meetings in Jefferson City, Mr. Chairman. We were made aware that there was a problem with who was going to hold title. There were many people who submitted requests to the State of Missouri to hold title to the property. However, the money had been appropriated, but the State did not want to take title to the property until the property had been acquired, so we had to find a titleholder.

The city of Times Beach submitted an ordinance to the State to hold title to the property until such a time as the buyout was complete. However, there were some problems with the ordinance. There was some concern that there would not be a city, that as each one of us were bought out we would move on. There would be no city officials. Therefore, without city officials how could there be a city to hold title.

However, the Governor finally did accede and the city was allowed to take title. But it was another 2 or 3 months haggling over who was going to take title. People at Times Beach have been on a roller coaster ride since day one of this. The title issue was a big issue in the State of Missouri.

Mr. **Levitas**. You describe the health impact that many people in Times Beach have experience, and you also made some reference to a CDC screening program, I believe, at St. Joseph's Hospital. Was this a treatment facility, or a diagnostic facility? Was this service provided by the Federal, or State medical authorities?

Mrs. **Leistner**. That was provided by both the Federal and State agencies, the Center for Disease Control, Missouri Division of Health. They held a screening at the St. Joseph's Hospital in Kirkwood, MO. Many people felt that the screen was a joke. They did not test but 60 people as far as blood work, skin tests, hair samples. There were 1,190 people who went through the screening. We do not yet have the results of those screenings.

Mr. **Levitas**. Do most of the residents of Times Beach so far as you know have adequate medical insurance to help them with their medical expenses?

Mrs. **Leistner**. Some do, Mr. Chairman, and some don't. In the case of my daughter, when she turned 19 years old, she was removed from our insurance policy because of her age. We appealed, as the union requested that we should. We got a letter from our doctor as to the condition of her health. We submitted all of this, and the fact that she was unable to work because of the seizure disorder, to the insurance company.

Unfortunately, she attempted to take her life in March. It wasn't until we submitted all the bills for the doctors and hospital that we learned that they did not put her back on our policy. So we have some 5,000 dollars' worth of medical bills that we are having to pay out of our own pocket. I am sure that there are many people there who are on fixed income, senior citizens who have. I know of one man who 2 years ago developed a seizure disorder at the age of 80. His wife also has many problems. And as you are well aware, their Medicare does not pay all of these bills. There is some $343 they have to meet themselves.

Mr. LEVITAS. History is full of examples of natural disasters, floods such as you had in Times Beach, hurricanes, tornadoes, earthquakes—acts of God. But there in Times Beach you got really, as you say, a double whammy. You not only had the problem of the flood, a natural disaster, but you also had a disaster that was a manmade disaster. This contamination by toxic chemical.

I wonder if you could give me some response to the extent to which the natural disaster contributed to your problems as compared to the manmade disaster. Which was the greatest, which is the most long range? And give me some sense of how man seems to have improved, if you will, on the ability to cause hardship and human suffering.

Mrs. LEISTNER. Sir, were it just for the December 5 flood, 95 percent of the community would have been rebuilt today. The businesses would be operating. It was the dioxin contamination that chased the people from their homes and closed the doors of the businesses.

Laine Jumper is here. He has talked with many, many people. He is very capable of giving you a very, very well-prepared answer to your question, if that is all right with you.

Mr. LEVITAS. Absolutely.

Mr. Jumper.

Mr. JUMPER. Mr. Chairman, I was building commissioner of the city of Times Beach for about a year and a half. We started, when I took over as building commissioner, cleaning the town up. It started out as a small river community. There were a lot of weekend homes and cottages and that sort of thing. Like the testimony said, we were transforming over to a lower middle-class community; a lot of new homes being built, a lot of things like that.

When the floods came, the flood water was in the town about 5 days. I think it would have left—we were back in about the 10th or 11th of December. Already at that time we had organized some 25 or 30 individual work crews to go in there strictly on a volunteer basis. There was no flood insurance available because Times Beach did not belong to the Federal program. But even without the Federal aid we had enough people, materials, donations, and that sort of thing, lined up to rebuild that town in less than 60 days.

We would have rehabbed most of the homes. Many of the homes were rehabbed by the owners, even during all of this going on, by themselves. There was all kinds of volunteer aid, like I said. Most of it organized and put together by the building contractors and concerned citizens of Times Beach. We would have done, taken care of our own needs without Federal aid, without State aid that we aren't eligible for, I believe, within 2 or 3 months. But when the dioxin announcement came, everything stopped.

The mayor used the word "incredible." That is exactly what it is. I myself had, I think, 11 or 12 crews of 6 or 8 craftsmen, each lined up ready to go on the 20th of December. The 23d that announcement came up and my phone rang off the hook. People said, "We just cannot go back in there. We can't go in there and do this for you. We are sorry." Church groups, unions, people of that nature were more than happy to give out of their heart to help us put the town back together after the flood, but when the dioxin hit that all stopped within 5 days. The town just sat there, and that was the end of it.

Mr. **LEVITAS**. Thank you, Mr. Jumper.

I just have one last question, Mayor Leistner. How would you describe your dealings with the Federal officials and State officials who were working with you to respond to the disaster? Was it efficient? Was it good? Was there smoothness? Could you just give us some idea of how this working relationship between yourself as mayor and also the citizens of Times Beach and the Federal officials, State officials, who were working with you?

Mrs. **LEISTNER**. At first it was absolutely incredible. We would make one phone call. At the onset of this there was nothing exchanged as far as paperwork was concerned. A call to the Governor's office, or call to Pat Brehaney at FEMA. We had anything that we needed. I think that we have found out since then that some of the things that we were told were untrue—well, I shouldn't say untrue, but I think answers were given when answers shouldn't have been given, because some of the officials were not aware of the Superfund laws.

But in February the businessmen were reassured that they would be reimbursed for their loss of income. However, we find out now that that is not true. They are not going to be reimbursed for their loss of income. As far as the emergency help, it was amazing, the help that we had. Everyone responded immediately to the phone calls from city hall. But it seems like in the last 2 or 3 weeks that response is getting slower and slower. I think everybody is very, very tired of hearing about the whole situation in the State of Missouri.

Mr. **LEVITAS**. Well, thank you very much, Mayor Leistner. I believe your statement, and I am sure the statements we will be hearing later today should provide not just the Members of Congress but everybody in America with a real understanding of why we have got to expand and extend the Superfund law. We are all Americans, and we share the loss and the suffering and the anguish that you have communicated. And we need to respond.

Mr. Molinari.

Mr. **MOLINARI**. Thank you, Mr. Chairman. Mayor Leistner, could you tell us how much the cost of the buyout was for Times Beach?

Mrs. **LEISTNER**. The Federal Government appropriated $33 million. The State matched that with 10 percent. I believe it is $36.5 million. That also involves the Minker-Stout site.

Mr. **MOLINARI**. Minker-Stout sites?

Mrs. **LEISTNER**. Well, yes.

Mr. MOLINARI. Does this cover all the area of contamination, or just part of it?

Mrs. LEISTNER. In my estimation there is no way that that amount of money can be—can reimburse the people for the loss of their health. Thirty-six million dollars is not near enough.

Mr. MOLINARI. Well, I understand that, but that is not what I am getting at. What I am suggesting is, that $36-plus million that is being spent, is that for one geographical portion of Times Beach, or is it all of Times Beach, or is it all of the affected area?

Mrs. LEISTNER. It was all of Times Beach. Everything within the corporate limits of the city of Times Beach.

Mr. MOLINARI. Now, is there any indication that the contamination has spread beyond the Times Beach area so that there may be a need for an additional buyout of other areas?

Mrs. LEISTNER. I am not aware of any other areas that are to be bought out at this time other than the Minker site.

Mr. MOLINARI. I have read, and wonder if you can confirm this, that the company responsible for the production of what was the dioxin eventually discovered at Times Beach could have legally disposed of that material for less than $100,000 annually. Is there anybody on the panel that can tell us whether that is accurate or not?

Mr. JUMPER. I am not sure about the figures, Mr. Molinari. But Mr. Bliss, Bliss Oil Co., that hauled this waste oil out of a Napaco plant that manufactured Agent Orange was paid to haul that away. Originally the Napaco people were contracting with, I believe, Rollins Co. in Louisiana, to have it incinerated at I am not sure how much per barrel, but they were paying a fairly high cost for it.

Your figure of $100,000, there was about 18,000 gallons of this waste oil sludge, $5 or $6 a gallon, that would be about $250 or $300 for a 50-gallon drum. I have seen somewhere in the paperwork we have come up with that Rollins at that time was charging about $400 a drum. So that is probably a very accurate figure. That it would have been disposed of for that much money.

But you have got to remember, Mr. Bliss was paid to haul it away, and he was paid by the city of Times Beach also to put it on the roads.

Mr. MOLINARI. I understand that. That is not unusual in this business of hauling toxic waste. They get paid to take it away, and then they get paid to dump it. But the fact is that we are learning that here is a concrete example of where for less than $100,000 the site could have been legally cleaned up. Through neglect, over $36 million has been earmarked, maybe not spent yet but earmarked, and that is not going to be enough to compensate, from what the Mayor said, the people for their true financial loss, leaving aside for the moment the health impacts and health injuries and medical bills that have been or will be incurred.

Mr. JUMPER. That is true. The State of Missouri has said that there are approximately 150 sites. Times Beach is one. Minker-Stout is another. That leaves the possibility of another 140 some potential sites, of which there are over 30 or more known. The mayor's brother lives on a site down in Castlewood. It is incredible.

Mr. **Molinari**. It has been estimated that the total cleanup will exceed $100 million. Now, I don't know if that is accurate or not. But when we compare what it would have cost to legally dispose of that material to what we have before us today, I think we have a concrete example of what the chairman was talking about.

I would like to change the focus for a bit. Mayor, attached to your testimony there is a letter, the Department of Health, Education and Welfare, Centers for Disease Control, dated October 2, 1974.

Mrs. **Leistner**. We attached that because of the date. The State of Missouri knew in 1974 that this problem existed and we wanted the committee to make note of the fact.

Mr. **Molinari**. We are making note of it. That is why I want to ask the questions which will follow. This letter is dated October 2, 1974, sent by the Center for Disease Control, Atlanta, GA, to the Missouri Department of Health. It talks about the contamination of the horse arena soil by TCDD, dioxin as we generally might refer to it. It talks about heavy concentrations, as high as 1,000 parts per million, which is very high. Then it goes on to say that there remains untouched in a storage tank in Verona, MO, an additional quantity of this substance, and recommends disposal through a reputable service.

The letter continues, and advises that prior to disposal, there be consultation with Dow Chemical in Midland, MI. I don't know if that would have been such great advice in light of other disclosures. Then it goes on to say that TCDD is a highly toxic material and its toxicity cannot be overemphasized.

The question I have, of course, is, do I understand correctly that the material that was still remaining in that tank was subsequently, together with the contaminated soil, brought to the Minker-Stout sites?

Mr. **Jumper**. No, sir; the spraying of the oil at the stables occurred in 1971. The soil from those stables was excavated after the horses died—I think twice—and wound up as residential fill at the Minker-Stout site. This took place in 1971 and 1972. It wasn't until 1974 that the TCDD was identified by the CDC as the toxin that killed the horses and made the children ill.

Mr. **Molinari**. What happened to the material, then, that was remaining in the tank?

Mr. **Jumper**. I believe the Missouri Department of Natural Resources, after 4 or 5 years of negotiations and testing, had it incinerated in Louisiana. The tank was taken to Louisiana and buried—and sunk in a bayou, I believe, way out somewhere in Louisiana. We were under the impression that that tank can be incinerated, but it wasn't. That tank still exists.

Mr. **Molinari**. Do we know where it is buried?

Mr. **Jumper**. I am sure that the Missouri Department of Natural Resources, and I don't know which State or Federal agency was involved in halting that thing, knows where it is. But it still exists and it is my understanding sunk in a bayou somewhere.

Mr. **Molinari**. Mr. Jumper, with respect to both the remaining residue in that tank referred to in this letter and the contaminated soil that they speak about, all materials were legally disposed of, is that correct?

Mr. **Jumper**. No; the soil I was talking about from the stables that were sprayed in 1971 was hauled and used as fill at the Minker-Stout site. That is how the Minker-Stout site came into being. Russell Bliss sprayed the horse arenas with this dioxin-contaminated sludge. There was almost a hundred horses that had died from three or four different stables. Soil from the Shenandoah stables, which is very close to where they lived, was hauled to that area and used as landfill.

Mr. **Molinari**. What I am trying to determine—maybe you can help me—the soil, the contaminated soil they are referring to here, was that properly disposed of?

Mr. **Jumper**. No, sir; it was not.

Mr. **Molinari**. Now, if the Missouri Department of Health had knowledge, as obviously they did by this letter, as to the seriousness of the material they were dealing with—and there are criteria here, recommended criteria for the disposal of it—why did the Missouri Department of Health not respond properly?

Mr. **Jumper**. I think the misunderstanding we have is that this letter is in 1974 and death of the horses and removing of the soil occurred in 1972, I believe. 1972.

Mr. **Molinari**. But this letter of 1974 referred to contaminated soil. The question was, after that, was any of that contaminated soil disposed of illegally?

Mr. **Jumper**. No, no; I don't know if it was disposed—nothing was ever done since. There is another letter from the CDC—I'm not sure if it is in here or not—that recommends that that soil be excavated and removed to a remote deep landfill somewhere away from these people. That was never done. They just left it sit. There was some controversy at that time about the half-life of TCDD. CDC recommended taking a test of dioxin levels and coming back in 6 months and 1 year, and testing again to see if it actually did degenerate in the soil. They took the first set of tests and that was the end of it. They never took the second set of tests, and the soil remains there to this day.

Mr. **Molinari**. Did anybody ever come back with a determination on what the half-life of it is?

Mr. **Jumper**. Originally, they tried to say it was from 6 months to 1 year. There is still some debate on that, but they know it is in excess of 20 years.

Mr. **Molinari**. Mayor, how many people are we talking about who are involved in Times Beach, roughly?

Mrs. **Leistner**. Approximately 2,200 people. Our 1980 census showed—was showing that we have 2,041 people living in the community, and we are estimating it at 2,200 people. But there are also a lot of people, telephone company, union electric workers that came into the community to work.

Mr. **Molinari**. This condition was discovered when, approximately?

Mrs. **Leistner**. We first learned about it in November 1982.

Mr. **Molinari**. When did that health screening that you talked about before take place?

Mrs. **Leistner**. That took place in January, February, and March.

Mr. **Molinari**. Of this year?

Mrs. Leistner. Yes, sir.

Mr. Molinari. I assume that a number of people have moved to other parts of the country?

Mrs. Leistner. There are only 14 families still living in the city of Times Beach.

Mr. Molinari. Would you know whether there is any system of monitoring those who lived there who were exposed to this TCDD and are now living in other parts? Are they being monitored? Is their health being checked periodically?

Mrs. Leistner. We are not aware of any monitoring. However, approximately 3 weeks ago at my home in Pacific, at my temporary home, a young man knocked on the door and he held some paperwork in his hand. I invited him in. It was a screening. Well, it was a questionnaire that is being provided by the Missouri Division of Health and CDC, some kind of comparison study. But as far as monitoring the people that have been exposed, I know of no system.

Mr. Molinari. Do you have a record of where the residents of Times Beach have moved to, their present whereabouts?

Mrs. Leistner. Yes, sir, we have a record. But it is incomplete.

Mr. Molinari. Has CDC or any other health authority asked you for a copy of these records so that they could communicate with these people from time to time?

Mrs. Leistner. No, sir, they have not. FEMA has a copy, or I have requested it from FEMA but they won't provide it because it would be a violation of the Privacy Act. But they have a lot of our people in temporary housing, and they have their new addresses. However, not all the people from Times Beach took temporary housing.

Mr. Molinari. So what we are talking about is a substantial number of former residents of Times Beach now living in other parts who may be exhibiting some signs of physical disability that could be attributed to the exposure.

Mrs. Leistner. Yes, sir. I have had people call me from California that moved away from Times Beach approximately 2 years ago telling me of health problems, deformities in children, and heart defects and diabetes. I have had people call me from all over the United States that formerly lived in Times Beach, and what I am telling them to do is to contact the CDC in Atlanta. And then I turn their name and new address over to the Missouri Division of Health.

Mr. Molinari. Has the regional office of the Environmental Protection Agency indicated any desire at any time to do a followup study on these people?

Mrs. Leistner. If they have I am not aware of it.

Mr. Jumper. Mr. Molinari——

Mr. Molinari. Yes.

Mr. Jumper. Could I make one comment about this health survey?

Mr. Molinari. Surely.

Mr. Jumper. When the health survey was first announced everyone in the city thought it was a good idea because of the confusion and fear and that sort of thing. When the first people went down to the health survey, to fill out this long questionnaire and sit down with a caseworker, the only things that they would include on that questionnaire are things that you could verify that you had been treated for by a doctor.

Originally most of the publicity was about this chloracne and skin rashes that were the only outward visible signs of dioxin contamination. Many of the people of Times Beach were poor and got by without going to dermatologists. When they got to the survey, these workers refused to put it down if they couldn't document it. The word got around within a few days that they were not interested in our medical problems, and that kind of messed up the viability of that health screen. Because the word got around that they weren't interested and many, many people refused to go to it.

One elderly gentleman that had a lot of skin problems for the last 5 or 6 years told me, he says, "I'm—I went down there and they didn't even write down, they didn't want to talk about what was wrong with me, so I'm not going." That got around and that caused a lot of the problems.

Another case, the Bothimer family discussed in the mayor's statement, they took their sons to a dermatologist on the recommendation of this health screening, medical people at the health screening. He diagnosed both their twins as having this chloracne, yet they still insist there is no chloracne in Times Beach.

Mr. MOLINARI. Who performed this health screening?

Mr. JUMPER. It was put together by the Center for Disease Control and Missouri Division of Health. There was another problem that came up in the health screening. The doctor put in charge of interpreting these results, Dr. Steven Ayres at St. Louis University Medical School in St. Louis, had testified earlier in 1982 at a trial that dealt with medical concerns from a dioxin spill at Sturgeon, MO. This doctor testified for the chemical companies and for the railroad company that dioxin was not harmful. He was their medical expert as to the lack of toxicity of dioxin. Six months later this doctor was appointed to the health screening to interpret the data for Times Beach at another dioxin site.

This word got around very quickly. People, there is very little credibility to the health screening from the people of Times Beach's viewpoint.

Mr. MOLINARI. In fairness to the other members of the subcommittee, Mr. Chairman, I am going to pass for the time being. But I would like to make the observation that it is rather shocking to hear that with all the notoriety we have heard about Times Beach and with all the various health related agencies that have visited the site, we are learning today that they really overlooked the health aspects. In some cases deliberately so, it seems to me. And to not follow these people and to create a medical history to determine what may occur, I think is inexcusable. We know in some cases these conditions may not show up for years.

I think that this subcommittee is going to try to get some answers from CDC and Missouri Health Department, and whoever else. I will defer now, Mr. Chairman, to the other members of the subcommittee.

Mr. LEVITAS. Thank you very much, Mr. Molinari. I think your observations are well taken.

Dr. Rowland.

Mr. ROWLAND. Thank you, Mr. Chairman.

Mrs. Leistner, I must say I am overwhelmed by the medical problems in Times Beach, MO. It is really almost inexpressible that so many illnesses occurred there. Over what period of time did these illnesses occur? Can you tell me how many years?

Mrs. LEISTNER. The dioxin-contaminated oil was sprayed on the streets in 1972, Mr. Rowland. And most of the illnesses that we have, most of the people that we have been in touch with who now have illnesses that may be dioxin-related started in 1974, 1975. And we even had a diagnosed case of chloracne in 1973.

Mr. ROWLAND. You mentioned problems in young people. One young person had a tumor on which there was still no diagnosis. There was no pathology report from the doctors indicating the type of tumor it was?

Mrs. LEISTNER. The doctor removed one very large fibroid tumor and his remark was there were seven other growths. He said I don't know what they were. I have never seen anything like them. However, I removed them.

Mr. ROWLAND. No pathology report on that, do you know?

Mrs. LEISTNER. No, sir, there were none.

Mr. ROWLAND. A group of 15 homes you said and 7 of the families had seizure disorders?

Mrs. LEISTNER. Yes, sir. In just one block of the community, there were seven seizure disorders.

Mr. ROWLAND. And breast cancer in young women some in their teens?

Mrs. LEISTNER. Yes, sir. A 23-year-old woman a month ago had a breast removed that lived on one of the hottest streets. In this report here, there is a report given by Mr. Jim Curtis, our water commissioner, who is also a minister in the community, of problems in his area of the community alone. He was telling me a month ago a young lady by the name of Rankins had a breast removed at age 23.

Mr. ROWLAND. This has been going on for 6, 7 years. Did insurance companies refuse to provide hospital insurance for the people that lived in Times Beach in view of all this, the problems they were having.

Mrs. LEISTNER. No, sir, not to my knowledge.

Mr. ROWLAND. They still provide insurance. What about life insurance? You would think life insurance with all the problems going on would rate people up that live in Times Beach.

Mrs. LEISTNER. That possibly does now exist. Many people in the community are concerned. And as well as the other dioxin sites, that the possibility exists in the future that because of the exposure to the dioxin they will not be able to acquire health or life insurance.

Mr. ROWLAND. But it has not occurred as of this point as far as you know?

Mrs. LEISTNER. No, sir, not to date.

Mr. ROWLAND. Mr. Chairman, it would certainly be interesting to get some medical reports. This is just overwhelming. I would really like to see some medical reports concerning these people in detail. I would hope that the subcommittee would be able to obtain some of those.

Mr. LEVITAS. Dr. Rowland, specifically I think in light of Mr. Molinari's questions and yours, we will be making specific inquiry of officials at CDC and Missouri health officials to get answers to these questions. In addition to that, tomorrow on the panel we will be hearing from some medical experts on both sides of the issue. And one of them at least was specifically involved in the Times Beach matter. So it may be helpful to ask questions tomorrow.

Mr. ROWLAND. Thank you very much. Thank you for being here all of you.

Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you.

Mr. Wise.

Mr. WISE. No questions, Mr. Chairman.

Mr. LEVITAS. Mr. Albosta?

Mr. ALBOSTA. Thank you, Mr. Chairman.

I want to compliment the mayor on her presentation. I think it was excellent. It reminds me of the time when I was chairman of a special committee in Michigan in the State house of representatives when I was investigating PBB. And it still remains somewhat of a mystery. Still we do not have in the State any agency that would respond quickly to the kinds of problems that you had at Times Beach or another PBB incident. So I just wanted to commend you.

I think anyone that wasn't moved by your testimony would be totally lacking in understanding of the kinds of problems that you have gone through.

Mrs. LEISTNER. I thank you. I might add here to the committee that, since the December 23 announcement of the dioxin contamination in the community and the fact that we have been in this tug of war—some doctors say it is harmful, some doctors say it isn't—the community has mail that has come from all over the United States. We have even been in touch with the Cremer Warner consulting engineering and scientists from the Italy incident. Also many Vietnam veterans have sent literature of all kinds. The city hall is stacked with literature on dioxin.

Of all the literature we have seen, all of them say the dioxin is harmful to your health with the exception of the American Medical Association's report which is attached to my statement.

Mr. ALBOSTA. If I might add to that, I don't think that the American Medical Association as such approved that. I think it was more the Missouri delegation that was in Illinois at that time. Certainly anyone that would look at the results of dioxin on animal tests would have to agree that it is a very toxic substance, particularly the one that is 2378-TCDD. We have some of that up in Michigan. I have worked and now have a study underway that is going to produce some results, I believe, in telling us the true facts about dioxin, how we should control it.

We have proper protocol, I believe, established for that. We are asking an arm of Congress to oversee that particular study. Then we are going to have the National Academy of Science give peer review on the study after it is completed. Recommendations will come out of that. That is not going to help you now in your present condition.

I think it is the responsibility of Congress to move as swiftly as we possibly can to avert and to help in problems such as you people have in Times Beach because you are not the only ones that are involved in this either, by the way. New Jersey has these problems, other places in the country, and I just read in this morning's New York Times that Austria has now shut down its last plant in Western Europe that produced dioxin as a byproduct from chemical manufacture. They have a process of burning that waste out in the North Sea on a ship.

Other areas of the country and world feel that it is a very toxic substance and that something ought to be done about it. Hopefully, your statement will get heard by more than just this committee here today. And that more people will be moved to do something to help people under the kinds of circumstances that you are in.

Mrs. **Leistner**. We in Times Beach feel that whether or not dioxin is harmful to your health because of all the conflicting stories, whether or not it is, the traumatic effect that it has on your life once you have been made aware that you have been exposed to it is overwhelming.

Mr. **Albosta**. I can understand that.

Mr. **Levitas**. Thank you, Mr. Albosta.

Congressman Young.

Mr. **Young**. Mr. Chairman, thank you very much. I just have a brief comment. I appreciate the opportunity to be able to sit with your committee today. I think as your committee, a suggestion I would have as your committee looks at the whole situation, you might want to consider field hearings in the Metropolitan St. Louis area so that you could bring all of the response teams that were suppose to be working. And I would have hoped would have worked a little closer together in the situation as it developed at Times Beach. Maybe your Oversight Committee, investigation and oversight, would like to try to get all those people together in the St. Louis area.

I think you will get a better picture. As I mentioned, this Times Beach and Minker-Stout seems to be a testing ground for EPA response, and FEMA and things like that. I want to compliment you again Mr. Chairman and ranking minority member for your interest in this particular problem.

Thank you.

Mr. **Levitas**. Thank you, Mr. Young.

Mr. Breaux, do you have any questions for this panel?

Mr. **Breaux**. No, Mr. Chairman.

Mr. **Levitas**. Thank you. Again on behalf of all of us and on behalf of the Congress, and I believe on behalf of the American public, you have our appreciation for coming and sharing with us the sad story of Times Beach. There is no doubt in my mind that your testimony here today will make a great contribution to an improved response by the Congress of the United States to deal with this problem, and not just for the future but, if possible, for those of you who are already victimized by this situation.

So I want to thank you and appreciate your being with us today.

Mr. **Albosta**. Mr. Chairman, I think the suggestion Mr. Young had was an excellent one, and would want to support his idea of moving the committee to the area. Let me tell you that what the mayor said about the psychological aspects is a reality. I think this committee could do a lot to help people understand what the problem is simply by having a hearing there and at least alleviate some of their concerns that no one cares. Hopefully we will be able to follow up eventually with proper legislation.

But I am sure with my experiences with the PBB incident in Michigan, the same thing was true. I held public hearings across the State to give people the opportunity to talk to their representatives. I am just sorry to say that nothing legislatively took place from our problems in Michigan to alleviate it. I hope that doesn't happen here. Those hearings would be very useful to help the people in the Missouri area.

Mr. LEVITAS. Thank you very much, Mr. Albosta. We appreciate your participation.

Mrs. LEISTNER. We appreciate the opportunity to be here today and all thank you very much.

Mr. LEVITAS. Thank you. I might say along the lines of Mr. Albosta's statement, I hope that you understand and will on our behalf communicate to the people of Times Beach that you are not forgotten people. We do care. And we will do what we can to deal with this problem, both for the future and the present.

Mrs. LEISTNER. I might say the people of Times Beach have become ardent fans of this committee. They watch you very closely in the newspapers and on television.

Mr. LEVITAS. Thank you.

Mr. MOLINARI. I just have a couple of observations I would like to make, Mayor. First, I want to thank Congressman Young and Congressman Albosta for their concern. This is not the first time that we have had the request to conduct field hearings at Times Beach. It is something we have been trying to do. But I do want to emphasize the fact that we are going to be following up with the Centers for Disease Control about health effects monitoring.

We do know one thing about dioxin. We know it is cumulative in the fatty tissues of the body; it builds up and remains for long periods of time. So it is kind of shocking that there isn't any monitoring. We are going to go into that.

Just one or two quick questions. You mentioned there was no flood insurance available.

Mr. JUMPER. No, sir; the city of Times Beach, through a nonbinding referendum elected to opt out of the Federal Flood Insurance Program because it would basically have shut the town down if we could not grow in any way at all. The people chose not to have flood insurance and most of them were willing to take that chance, live on a river and take the chance of the flood. Many long-time residents had seen one major flood in 1957. You need to understand that the people of Times Beach just weren't worried about the floods. We would have recovered. We would have made it.

Mr. MOLINARI. I just wanted that for the record. How about private insurance?

Mr. JUMPER. There is no private flood insurance available. The Federal Government subsidizes all flood insurance and regulates it.

Mr. MOLINARI. I am not talking about flood now. I am talking about beyond flood damage. Was there any private insurance available?

Mr. JUMPER. No, it is kind of interesting. Shortly after the flood I became a rather public figure in all of this, somewhat regrettably to my wife. But I became very unpopular with a very small group of people that just didn't want to hear anything about anything in the town. And about a week after the flood my home was vandalized. Not only with the flood damage but they broke out all the windows and a lot of other vandalism. My homeowner's insurance refused to pay for it simply because it had been flooded, and they said it was from the flood. Homeowner's insurance was being canceled by the insurance companies until the State division on insurance put a stop to it.

Could I share one final point with the committee here? The international aspect of this publicity I hope won't reflect poorly upon the Federal response. But we received a letter from the Cremer Warner Co. that did the engineering studies about what to do in Italy. They wrote us a letter and said, this man said, "Although I write from several thousand miles away from Times Beach I have been appalled at the press reports on the dioxin disaster that have struck your town. I also read with interest news of the personnel of the Federal Environmental Protection Agency and felt that you and your colleagues could well need alternative expert advice concerning this dioxin problem."

The Federal response has been good. We appreciate the fact that they are going to pay us for our real estate. But what we would really like to see, most of the people would have liked to have seen the town relocated like it says in the Superfund law. But I think it needs to be looked at, too.

Mr. MOLINARI. One last question. Business insurance. Were there any insurance proceeds for business to pay for interruptions?

Mr. JUMPER. I was overinsured as a contractor. I had every kind of insurance there is, but I think they used the flood as an excuse and refused. In one instance I had a big pile of material, homebuilding materials that floated away and knocked another man's home down completely. They refused to pay for it complete.

Mr. MOLINARI. I wasn't asking about you only. Was there any kind of insurance anywhere?

Mr. JUMPER. No.

Mr. STONE. There was 347 mobile homes in the park. Mobile homes in the State of Missouri are treated as personal property. About 85 percent of those people did have flood insurance.

Mrs. LEISTNER. It was covered under the comprehensible part of your policy.

Mr. MOLINARI. So they did effectuate some kind of recovery?

Mr. STONE. True.

Mr. MOLINARI. Thank you very much.

No further questions, Mr. Chairman.

Mr. LEVITAS. Something you said just now triggered a question in my mind. The $33 million figure which was contributed by Superfund, do you know how that $33 million figure was arrived at?

Mrs. LEISTNER. I might just probably guess on that. It has never been confirmed. But at the onset of this we submitted this folder to the President of the United States. In the folder you will see the businesses of Times Beach, their property value and their gross yearly income. Then we were told that they estimated each home at $40,000 and somehow arrived at this figure.

Mr. JUMPER. I might add when I came to Washington for the one meeting we had here on President Reagan's Times Beach Task Force, they asked me what I thought it would cost to purchase the real estate in Times Beach. I told them somewhere around $35 million. That is very close to what they have come up with.

Mr. LEVITAS. In other words, the $33 million that has been committed from the Superfund is for the items you have just described. It doesn't have anything to do with a cleanup of the problem that is there.

Mrs. LEISTNER. No, sir, it does not.

Mr. LEVITAS. So it doesn't even address that, nor does it provide any compensation for those other health matters, personal property, loss of income.

Mrs. LEISTNER. No, sir.

Mr. LEVITAS. It is just as we both said, the tip of the iceberg.

Mrs. LEISTNER. Correct.

Mr. LEVITAS. Congressman Young, you wanted to add something.

Mrs. LEISTNER. Congressman Young was just telling me that he was responsible for that figure. They took 800 homes at $40,000 each, and that is how they arrived at the $33 million. $32 million.

Mr. YOUNG. That is not an expertise as you well know, Mr. Chairman. But it was confirmed by some other agency after my office, I asked them early in December to try to come up with a figure of what a buyout of the whole town would cost as far as the real estate. They took the 800 homes and worked out about a $40,000 figure. Somebody else reiterated that figure later in January.

Mr. LEVITAS. I see.

Mrs. LEISTNER. We were advised it was because of this report. Then the balance of the homes, because 337 of those homes were mobile homes and 85 percent of those people were covered by some insurance.

Mr. LEVITAS. Still, it just doesn't deal with the problem that still is there on the ground, nor does it fully compensate or make whole, as you pointed out.

Mrs. LEISTNER. No, sir, it does not.

Mr. LEVITAS. Thank you very much. We appreciate your being here.

Mrs. LEISTNER. Thank you.

Mr. LEVITAS. The next panel of witnesses, if they would come to the witness table, consists of Shirley and Ronald Payne of Pacific, MO, Rita Jones of Staten Island, NY, John Hollingsworth and Drew Rainer of Lake Charles, LA. I want to express my heartfelt appreciation to each of the witnesses who are appearing before us today.

Also, I want to welcome a Member of Congress, a colleague who is here in the room today who has asked to say a few words of introduction about the people who are testifying this morning, and with respect to the issues that this subcommittee is attempting to address.

We will begin with Congressman Gephardt, who has been here and listened to the earlier testimony. We appreciate your participation.

TESTIMONY OF HON. RICHARD A. GEPHARDT, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF MISSOURI

Mr. GEPHARDT. Thank you, Mr. Chairman, members of the committee. I really appreciate your continuing attention to this problem as it presents itself in Missouri and across the country, and believe that the faith of our citizens in the Government is immensely helped by the work of this subcommittee, in trying to understand the problem and trying to fashion solutions to the problem.

I think the people that are here today from Missouri who are constituents of mine, Shirley and Ronald Payne, bring to us a very important message regarding what is obviously a pressing and difficult problem, and one that will be with us for decades to come. I was interested in your trying to figure out what the costs are going to be. When I just look at the costs down the line of the total Missouri problem with just dioxin, I see figures that would exhaust the Superfund with Missouri alone, if present technology is as expensive as I think it is in dealing with doing something with the dioxin.

The message this panel brings to us is that the past practices of dumping of our hazardous wastes in a haphazard way has some very real side effects. It impacts the health and welfare of tens of thousands of our fellow citizens, if not more.

Mr. Chairman, I have only taken a deep interest in this issue during the last year. While Love Canal was a tragedy, I guess in Missouri we never thought that it would happen to us. However, it has and in recent months we have found numerous hazardous waste sites throughout the country with many more still to be discovered.

In my district alone there are several sites that are contaminated with the chemical dioxin. Throughout the State of Missouri more than 30 sites have been uncovered in the past year with another 100 or more sites still under investigation. All of these sites are the result of haphazard dumping by only one waste disposer; who knows what else lies within the confines of my State and others.

Although we have been able to get some action on a few of the sites within our State, that has only been through constant efforts by the entire Missouri delegation. At some point the present system which we have set up to address these problems will not be able to cope. Already strains are being felt.

One of the major problems that we have is that the science on the chronic health effects of many of our wastes is not clear. On what is known as the Minker-Stout site in my district, the EPA finally offered permanent relocation assistance to 11 families. Yet, families living just a few feet away from levels well in excess of the acceptable level which the Centers for Disease Control has adopted will receive no assistance at all. These families are forced to live just a few feet away from a very grave risk and, in my mind, there is no doubt that they are being subjected to undue health risks.

At a meeting in my district earlier this year several residents asked the officials involved in making the decisions on this issue whether they would live there. To a man, each official said that if it was them, they wouldn't live across the road from the Minker-Stout site. I might say parenthetically that the Payne family, until about a year ago, lived across the street from the Minker-Stout site. What you are going to hear today are the physical problems they experienced living 20 feet from the high levels of dioxin. That is why I have been asking EPA to do something about the families that have lived in the very near proximity of this site.

We have asked that a "zone of safety" be created around the site to guard against the risk several years from now, upon finding out that dioxin is much more toxic than we had once thought, that we had made the wrong decision. The cost of relocating just a few more families is minimal in relation to the eventual health problems they might incur.

I know that you and the members of your subcommittee have been addressing this problem for some time and are much more experienced in this area than I. However, I would like to offer an idea which I think will address some of the problems arising out of our numerous waste sites. A system such as the national flood insurance system in scope could be set up to address the long-term health problems coincident with our waste sites. Premiums could be paid through a variety of sources: the Superfund, HHS, and the States in which a site is located.

The residents at and near these sites, within a "zone of safety" would then be afforded long-term health care for their problems arising out of the site. To address the problem of how to measure a "zone of safety," a concept similar to that used by French electric companies in charging for electrical service might be applied. The closer an individual lives to a nuclear powerplant, the cheaper the cost of their electricity. Thus, as an individual lives farther away from the site, they may be asked to pay a portion of the premium out of their pockets.

I don't know if our Nation can financially cope with compensating individuals with money damages for the damage they have incurred. We can, however, ensure that their long-term health problems are addressed.

I apologize for taking up so much of the subcommittee's time. I am going to have to run out the door for a hearing with my own committee, but I appreciate having my constituents and other constituents from around the country here to better understand their problems.

Mr. Levitas. Thank you very much, Dick, for your statement and for introducing the Paynes to the subcommittee today.

Your suggestions are very provocative and I think should be considered as one of a number of possible ways of responding to this cause, you are quite correct. Just based on what we know about the cleanup, forgetting everything else, just the cleanup, the Superfund will not clean up half the priority sites already identified, 419, and that represents a fraction of the sites we already know about each day.

And each day there is a new one.

As I pointed out this morning, the headline in the Atlanta Constitution was the discovery of an abandoned hazardous waste site that apparently is leaching into the soil.

Your suggestion is one we certainly will consider. I appreciate your being here.

Mr. **Gephardt**. Thank you.

Mr. **Levitas**. I think we will introduce all the witnesses and then let them speak as a panel. So at this point I would like to now call upon our colleague and member of the subcommittee, Congressman Breaux, who has constituents here today, but also because Congressman Breaux has truly been one of the leaders in the Congress in dealing with this matter of Superfund and hazardous waste sites.

As I recall, Congressman Breaux managed Superfund legislation when it came through this committee and has recently introduced other legislation that is extremely important. I will let him talk about it if he so chooses. But he has truly been one of the people in Congress who early on saw the problem and for a long time was a voice in the wilderness.

I am grateful for his continuing interest and participation today. I recognize the gentleman from Louisiana.

TESTIMONY OF HON. JOHN BREAUX, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF LOUISIANA

Mr. **Breaux**. Thank you very much, Mr. Chairman. Also thank you for your very generous words. I know some people think I am still in the wilderness, trying to come out, but you are correct in the sense that when we did first draft Superfund legislation, the real goal at that time was to try and find a quick way of addressing the cleanup problems we had in this country.

Quite frankly one of the missions at that time was the failure of the Superfund to include any kind of compensation system within the structure of the fund for victims of these toxic waste sites throughout the United States.

I would commend the chairman and members of this subcommittee for addressing the serious problem of—after we clean up the sites—what do we do for the people who have suffered injuries who have no other recourse to turn to as far as getting their injuries taken care of.

I think one thing we have been learning, Mr. Chairman, is, while we have been focusing the last several years on toxic waste and EPA problems, one thing we have, I think, found very clearly is that most of the problems that we are finding in the United States are coming not from illegal dumpers who go around at midnight and dump toxic wastes in ditches and canals, but most of our problems are coming from legally permitted waste sites.

Companies have gotten a permit from the Federal Government. We in the Federal Government have given them a permit and we have said it is all right to go dump in this particular place, and those are the type of dumps causing the injuries we are hearing about in this country.

It means we need to change the way we have been doing things. I have introduced legislation and will be offering that bill as an amendment next week on the House floor, which would eliminate all land disposal of liquid hazardous waste.

I feel very certain that unless we set some standards and deadlines, companies are going to continue to use the Earth's surface as a means of dumping liquid toxic waste.

We have found no matter how safe people tell us it is, it has not been safe. We have people like the witnesses today who are up here telling us some real horror stories about problems that have occurred many times from a waste site that we in the Government have said it is all right to put there. That is certainly not acceptable.

The interesting argument that some people make is that, well, it is going to cost too much if we can't dump it in the ground.

I would only submit that if we look at the costs these people have incurred, if we look at the fact we have had to buy up an entire city like Times Beach, if we look at the destruction of natural resources and look at the loss, look at the emotional and mental problems people are having as a result, if you put a bottom line on a cost figure for what that would cost, I would dare say alternatives that are available today are a lot cheaper in the long run than the method we are using right now.

So, Mr. Chairman, I think that you are moving in the right direction towards compensation as part of a Superfund because, without it, these people are going to have no place to turn.

I would just in the way of introduction, we are very pleased to have two people from my district, Lake Charles, LA. Mr. Drew Ranier is a prominent attorney, a good friend of mine from Lake Charles, who not only is involved with representing Mr. Hollingsworth this morning in the claims for personal injuries, but has also been a leader in the movement.

That is not something he has taken up just because of this incident, but is a real leader in the movement in southwest Louisiana to try and bring about rational policy toward regulating hazardous waste. It is those types of citizen movements that are really going to, I think, ultimately get us to do what is right. We are pleased to have both Mr. Hollingsworth and Drew here this morning. Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you, John.

The next person I want to recognize is the ranking member of this subcommittee, Congressman Guy Molinari of New York.

Let me say publicly that Guy Molinari is personally responsible for the entire investigation into the EPA Superfund program and hazardous waste. It is almost 2 years ago that he first called the matter to my attention.

At his persistent urging, I went to Staten Island to see for myself the problems of hazardous waste disposal as it exists in the Metropolitan New York City area. I was so shocked by what I saw on that occasion that I promptly ordered the commencement of hearings which began really at the end of 1981. What has happened since then is commonly known history.

So all of us owe Congressman Molinari a great vote of thanks, not only for his continued interest, but I think very importantly and significantly the fact that he was the one who was the cause of getting this whole situation under the spotlight of public scrutiny.

It proves to me that one person can make a difference, and a big difference.

Congressman Molinari, you are recognized for purposes of introducing your constituents, and if we have some hard questions we will ask you.

Mr. Molinari. Well, I am just about speechless after those kind remarks, Mr. Chairman. I appreciate it. While we are throwing bouquets around, it should be recognized that without a chairman who was responsive we wouldn't have been able to accomplish what we have accomplished.

I would also like to pay tribute to Mr. Breaux, because the subject we are discussing today, victims compensation, was included in his original legislation. If he had his way, and supporters of his legislation, it would be law today. Unfortunately my understanding is that it was stopped in the Senate.

Mr. Chairman, I would like to introduce the next witness, the lady on my left, Mrs. Rita Jones. Mrs. Jones is one of the founding members of a Staten Island community group called IRATE, a group formed after it was revealed that toxic waste dumping had taken place on a large scale in the Brookfield Landfill. This is a New York City garbage dump about a block from her home.

Her testimony, Mr. Chairman, will be a classic illustration of what happens to a family living near a toxic dump. It will be a presentation filled with the frustration and despair that perfectly innocent people face when they are confronted with a maze of agencies and bureaucracies that seem indifferent at best, callous at worst. There is a Rita Jones in every congressional district in this country, Mr. Chairman, because the problem of toxic waste dumping affects every district in the Nation. Her story is one of individual tragedy but is also one being played out in thousands of homes across the Nation. In small towns, rural hamlets and sprawling cities, people like Mrs. Jones are experiencing the same fears and frustrations you are about to hear.

She is representing not only herself but thousands of families in every State who are trapped and asking for help. Mr. Chairman, there are many important issues in this country that affect people in any number of ways. But few issues are as tragic as that of the families that are caught up in the web of toxic waste dumps.

It strikes on things they care about most, their children, their health and their homes. And Mr. Chairman, if I may, just so you and the other members of the subcommittee can have a perspective as to what she is going to talk about, we do have two blown up pictures here showing the residential community where Mrs. Jones lives. In the foreground is the Brookfield dump. The pictures show a ditch that is 100 feet wide, 30-some-odd feet down, that was dug through a municipal landfill.

Testimony in a Federal court and in the New York State Supreme Court indicated that there was dumped illegally between 3 and 10 million gallons of toxic chemicals. Interestingly enough, Mr. Chairman, they were dumped by tank trailers which are not legally allowed in a New York City garbage dump. So we had five tank trailers a night for a year and a half during the week, and usually nine on a Saturday and Sunday night, going in and out of that dump.

There have been people put in jail as a result. There were payoffs, corruption—government at its worst. But here you have the residential community a stone's throw away. From the dump to the street is about 200 feet. And this young woman is going to speak for herself and for the families and friends in her neighborhood, Mr. Chairman.

I know she is a little nervous about being here today, but I know her message is an important one and I thank her very much.

Mr. LEVITAS. Thank you, Congressman Molinari.

Before we hear from the panel I observe there is a recorded quorum call taking place on the floor of the House. Rather than unduly interrupt the presentations of the panel of witnesses I would suggest that we briefly recess and then return without delay to commence their testimony. I will say that during the course of the proceedings on the floor today there may be other votes. It is just the way business works around here. From time to time we will have to take recesses of this sort. I hope they would not be unduly intrusive. Every time I say that I am proven wrong, but we will do the best we can, and appreciate your indulgence.

The subcommittee will stand in recess for 10 minutes.

[Recess.]

Mr. LEVITAS. The subcommittee will please come to order.

At this time I would like to welcome all of the witnesses at the witness table today. As I said, we are very appreciative for your making the effort, as well as the personal sacrifice to be with us today, and to share with us your experiences so that we might better understand the dimensions of this problem as it affects human beings and thereby be better able to respond.

So with those few words I would first like to ask Mr. and Mrs. Payne if they would proceed.

TESTIMONY OF SHIRLEY PAYNE AND RONALD PAYNE, PACIFIC, MO

Mrs. PAYNE. I would like to thank you all for inviting my husband and me here today. At first, when I was asked to appear, I was hesitant because I had never spoken before a group as large as this and because I had never even been on an airplane.

But, Mr. Chairman, I began to think—my family has experienced many health problems which, I believe, are associated with having lived across the street from the Minker dioxin site. If, by telling our story, it will help us, our friends and acquaintances, and those who are or will be in the same situation, then it is worth it all. And that is why we are here today.

In June 1975 we bought a house on 4038 West Rock Creek Road in Imperial, MO. We lived there 6½ years until we moved out in November 1981.

Our house was located across the street from property owned by Harold Minker. It was on the Minker site that dioxin-contaminated dirt from the Bubbling Springs horse stable was dumped.

Being across the street from our home, it was also where my four children waited for the school bus and played. For 6½ years we breathed the contaminated dirt and dust from the Minker property.

As I mentioned earlier, I believe our family health problems have been a direct result of our exposure to dioxin. I would like to tell you about these. In doing so, I have tried to recall the exact time to the best of my recollection. In any case, I have some of our hospital records with me today, and I would be happy to submit them for the record.

Beginning about 1978, I began experiencing respiratory trouble. On three occasions, I couldn't hardly breathe, and Ronny had to rush me to the emergency room at St. Joseph Hospital in Kirkwood. I visited the doctor's office several times for this, and was given shots and medication for 7 or 8 weeks.

Since 1978, I have also had constant drainage of the nasal and throat area, so much so that the only way I can sleep many a night is sitting straight up in a recliner, as my doctor requested that I do.

In 1978, I was hospitalized for poor circulation and tested at St. Joseph Hospital for the possibility of blood clots in my legs. I spent 10 days there at that time. The doctors could not determine the cause of the swelling or the lack of circulation.

In 1982, I went to St. Joseph Hospital emergency room for a bleeding kidney and bladder problems and was placed on medication. During that year I was also treated for sores that left scars. The doctor said he had no idea and no answer for them.

In 1983, I was tested by Dr. Fisher from CDC. He told me to have an echocardiogram, and I was detected to have high blood pressure and an extremely nervous condition, which, he said, I should have checked. Also, Dr. Sage of CDC took immunity tests in our home and immediately he was concerned about how my tests reacted and was at my house the next morning to look at my arm. He was concerned by the way it looked. Not all of our results of the other CDC tests taken in February 1983, liver and immunity tests, are back yet.

My husband, Ron, has also had a number of problems. On November 1, 1981, he experienced swelling of the face, lips and eyes which lasted for 2 or 3 months. His eyes were at times swollen shut. He went to the hospital and doctor's office a number of times for this. At first we thought it was allergies. He got shots and we checked everything in the house—furniture, everything. Eventually the swelling went away, but one day he went back to the Minker site and before we got home, he noticed a rash coming on his arms, face, and neck.

In 1982, he completely lost his voice for over 5 weeks and was still hoarse for about 3 months after. He has nasal and throat drainage that keeps his throat sore, and bronchial troubles which medication does not seem to help.

In May of this year, he was admitted to Normandy South Hospital with severe headaches. No medication would relieve the pain. They ran all kinds of tests and diagnosed his condition as cluster headaches, for which he is now on medication and oxygen. In fact, we have an oxygen tank in our home, and whenever he gets these headaches, whether at work or someplace else, he has to come home and take oxygen for 15 to 20 minutes. Nothing else will relieve the pain.

In addition, my four children have experienced numerous problems. Ron, Jr., who was 17 years old when we moved across from the Minker site, has had respiratory trouble, severe stomach pains and numbness of the entire body. He visited St. Joseph Hospital twice in 1979, and once in 1980. Like the rest of us, he has repeated throat infections and colds. Medicine does not seem to help. I also want to add that his child, a baby of 8 months, already is experiencing severe immunity problems. He can't seem to fight colds, and all of us are very concerned about his fragile state. He has been to the doctor's office eight times already and taken to the hospital twice. Before he finishes his medication, he has got another virus, or bronchial problem. That is just the way it is.

I have one daughter, Kathy, who was 11 years old at the time we moved in. Kathy has had her nose cauterized for nose bleeds, but the past several years her nose has bled more often and lasted much longer than before. She will just be sitting and her nose will start to gush.

In 1978, she was diagnosed as having an enlarged pulmonary artery. She still has severe chest pains and shortness of breath.

In December 1982, she was rushed to the hospital because of severe stomach cramps, admitted and placed immediately on IV's for a 4-day period, and diagnosed as having hemorrhagic cystitis and influenza. Five months later, she again suffered severe stomach pains and this time her M.D. sent her to a specialist, and she was diagnosed to have hemorrhagic cystitis again. She is still on medication and being treated. A week and a half after she came out of the hospital for hemorrhagic cystitis, she came down with strep throat, even though she was still on antibiotics.

I am concerned about her weight loss. Since her hospital stay in December, she has gone from 130 pounds to 116.

This past February, she was tested by CDC and hasn't got all the results back yet. She was seen by Dr. De Val from CDC for growths on her face and neck. The medication did remove most of them, but now they are coming back. She is allergic to penicillin, Keslin, Keflex and IVP dye. She also shows reaction to insect bites. She has had her share of sore throats, too.

My son, Ricky, who was 4 years old at the time we moved in, has had throat infections, and it got to the point that medication would not clear up these infections. So, on April 14, 1980, Normany Hospital removed his tonsils. Then, 8 days later, at 3:30 a.m., he started vomiting blood and we rushed him to the emergency room. They removed four blood clots the size of grapes from his throat. In August of that same year, 11 teeth had to be removed for unknown reasons, although he had had regular checkups at the dentist.

In 1980, he was diagnosed by Dr. Spain as being anemic, for which he is still on medication and has blood tests run every 6 months. In 1980, Ricky's teacher at school complained about his nervous condition. She suggested he be seen by a doctor, which I did. He put him on nerve medication. He has also had stomach problems and headaches.

My last son, Chad, who was 10 months old——

Mr. LEVITAS. Just take your time.

Mrs. PAYNE. My last son, Chad, who was 10 months old at the time we moved in, has had health problems, also. He had severe stomach pains, diarrhea and vomiting. His doctor was concerned and sent him to Cardinal Glennon Children's Hospital for further testing. They did surgery on him in October 1980 and removed three growths from his small intestine. He still suffers severe stomach pains, diarrhea, and is often sick to his stomach.

In September 1982, he was taken to the hospital for respiratory problems, where x rays revealed signs of enlargement of the heart, expanded lungs, and acute bronchitis. He has experienced sores frequently on his upper eyelids. I have talked to the doctor about this condition and he has prescribed medication.

Mr. Chairman and members of the committee, our family has gone through a lot. It seems that at one time or another, one of us is sick. I am always running off to the doctor, and it has been very frustrating. We have seen many doctors and specialists, but each time we ask what is causing this, they don't know. As I noted to you earlier, the final results of all the CDC tests are not known as yet, but I would point out that we received a letter from the State health department which indicates that there is a strong possibility that dioxin is the cause of our problems.

I am concerned about my family and about my friends and neighbors, who have all experienced similar problems.

Again, as I said in the beginning of my statement, we moved from our home near the Minker site in November 1981. Since this was before the dioxin issue became public, we were fortunate enough to be able to sell our house without a loss. However, it has not been fortunate for the people who bought our house. First of all, they have a 6-year-old son who was born with spina bifida. He is now living on one kidney. They are very concerned, living 80 feet from the contaminated dirt, about his condition, which is getting worse. Second, even though they would like to sell their house because of the dioxin issue, it is almost impossible.

Murray Abrahamson, who lived next door to us, has been checked by CDC and his results came back as having extremely high cholesterol. His reading from CDC was 416, when a normal reading should have been around 250. Also, his triglycerides were extremely high at 2,140 when a normal reading should have been around 150. He is under constant doctor's care as is his son Duane, who has experienced severe headaches, nausea, and stomach pains, and his wife, Shirley, who, in the late 1970's, started having headaches and numbness of the hands, face, and feet.

Even though we haven't experienced property losses, to the best of our calculation the last 6½ years have cost us at least $25,000 in medical expenses not covered by health insurance.

Finally, I am concerned about the other people who still live near and around the Minker site. The contaminated dirt is still there; there are no fences and no warning signs. Some of the houses on the site are being bought out, but those across the street, like my former residence, won't be because EPA is using the street as the cutoff point.

Mr. Chairman, this is our story and I appreciate the opportunity to tell it.

Mr. LEVITAS. Thank you very much, Mrs. Payne, for sharing this with us. I know it is very painful for you to have to recount it. But as I said earlier, what you are saying today makes a great deal of difference in giving us a real understanding just what people have experienced in terms of health and economic loss and psychological pain.

We will have some questions in a few minutes. But at this time I would like to ask Mrs. Jones if she would share her experiences with us.

TESTIMONY OF RITA JONES

Mrs. JONES. Mr. Chairman, members of the committee and staff, my name is Rita Jones. I want to thank you for inviting me to testify before your committee. Frankly, I never dreamed that I would ever be in this position.

I was born and raised in the Flatbush section of Brooklyn, NY. It is a crowded urban area—an area where I did not wish to raise my children. I wanted my own house with a little lawn on which my children could play. I wanted to belong to a pleasant community of friends and neighbors—a community that was safe, clean, and enjoyable. So, in June 1977, when my daughter Dana was 6 and my daughter Stephanie was 3, we moved to 112 East Brandis Avenue on Staten Island. In short, I thought I bought the American dream.

We moved into this area because it was a new development consisting of young families such as mine; because the area was open and green; and, in contrast with my city experience, looked and felt like heaven on Earth. As I recall that time and the pleasant anticipation of a new life we all experienced, and I compare it to the problems and uncertainties over our health with which we have been forced to live, I cannot help but feel a sense of despair.

I wanted to bring my children out of the crowded, dirty urban sprawl so that they could grow up in a healthier environment. Instead I have two children who suffer recurrent upper respiratory infections, high fevers, nose bleeds and now asthma.

One of the more pleasant aspects of living in a small community is the daily meeting of mothers waiting with their children for the school bus. The conversations during these times naturally center upon the children and the family. It was during these chats in the month of January 1982 that I and other mothers in the community discovered that our children were getting ill at an alarming rate and that they were all experiencing much the same illnesses—skin rashes, nose bleedings, unexplainable bouts with high fevers, and increased asthmatic attacks.

It was also in January 1982 that the city had started excavating a trench through the Brookfield dump. It is quite a trench, measuring about 100 feet across and tapering down in a "V" shape. It extends roughly 30 feet below ground level. For your convenience, I have brought a number of photographs of the Brookfield dump area showing the trench and its proximity to my community.

At first no one thought that there might be a relationship between the digging in the dump and our illnesses. It wasn't until January 15 that we put the two events together. On that day our neighborhood was literally attacked by an odor so strong that no one could go outdoors without immediately being seized by a fit of coughing and gagging. Even indoors the stench was so overpowering that many of us gagged and retched.

I called my neighbors, and we compared notes on what was happening in each household. What we discovered was startling. Beyond the symptoms of gagging, beyond the physical vomiting that was affecting almost everyone, the other mystifying illnesses that had recently appeared were occurring in full force. Children and adults together were suffering from eye irritations and skin irritations. One child had developed a fever and a number of children were experiencing asthmatic symptoms.

Together, over our phone network, we pieced together these individual events and came to the realization that the Brookfield dump was probably causing our problems.

In 1980 during a trial in Pennsylvania, a man named Russell Mahler testified that truckloads of toxic wastes had been dumped into the Brookfield dump. The news of this illegal dumping was uncovered by the Staten Island Advance and a story about this toxic waste dumping was published just a few days before the odor attack of January 15.

On January 15, someone mentioned the illegal dumping and wondered out loud if our neighborhood was being exposed to toxic chemicals. I can assure you that nothing I have ever experienced in all my life has ever frightened me so much as the thought that what I and my children were experiencing was not being caused by nature, but was a result of something being carried on the air into my home to attack us.

Fear set in very quickly, but fortunately, in our case, it propelled us into action. I called every local, State, and Federal agency, every elected official I could think of, the Health Department, the environmental agencies, the Interstate Sanitation Commission, my councilmen, assemblymen, and my Congressman. Every one of these agencies responded in a disinterested fashion. They took the information and promised to investigate. Some of the agencies went so far as to tell me that they were aware of the odors that were coming from the excavation in the dump and suggested that we should be patient and wait for it to go away.

No one wanted to hear anything about toxic waste dumping or the possibility of our illnesses being a result of exposure to toxins. No one except Congressman Molinari. Within an hour after I spoke to the Congressman, there were three cars, one van, and seven men representing various city, State, and Federal agencies, all running around my neighborhood taking all kinds of measurements. But, after this brief flurry of activity, everyone disappeared, and no one was willing to talk to us and help answer our questions concerning the possibility of our whole community being exposed to toxic chemicals.

In fact, the sanitation commissioner publicly called Congressman Molinari an alarmist for expressing concern over the possible level of contamination at the Brookfield dump. In an effort to establish the cause of our illnesses, Congressman Molinari arranged to have nine women tested at our local hospital.

The results of our blood tests showed that three of us, myself included, had high white blood cell counts. One woman had problems with her liver. The doctors were puzzled as to the cause of these results, and while they could not say with certainty that we had been exposed to something in the air, they agreed that toxic exposure could produce our results.

We continued making phone calls seeking help in determining whether the illnesses we suffered from were a result of the trench construction. It is only one block away, and each day hundreds of cubic yards of possibly toxic dirt were dug up and tossed onto a mound.

Finally, Dr. Stephen Schultz, an epidemiologist from the city health department, visited the neighborhood to survey the area.

After visiting the area and interviewing me and others, Dr. Schultz said that he was concerned about our health. He said that, he was less than confident about the air samples taken by the EPA and not sure he agreed with their findings. He said that at that point no one should be saying that there were no other dangerous toxic substances being emitted.

We didn't know whether to laugh or cry when Dr. Schultz made his statements. Here was a member of the New York City Health Department saying to us that there was a chance that we were indeed being exposed to toxic material. I, at least, believed that now our officials who had held back waiting for some evidence would do something to help us. Nothing happened.

In March 1982, 2 months after these illnesses started, a group of my neighbors and I met with City Sanitation Commissioner Norman Steisel. We pleaded for his help. Mr. Steisel assured us that the department would look into the matter, but cautioned us to remember that the toxic dumping was only alleged. We all pointed out that the neighborhood was experiencing unexplainable episodes of dizziness, nausea, high fevers, and chest irritation. Our pleas fell upon deaf ears. Commissioner Steisel, after listening for roughly 45 minutes, asked to be excused so that he could attend another meeting.

On April 1, 1982, desperate to make our plight known, some 300 people from the Brookfield dump area staged a demonstration to force a halt to the sewer construction.

We marched at the entrance to the dump. We were all determined to get some help. We are not professional pickets. This was the first time any of us had done something like this. The police, though sympathetic, were instructed to be firm. They warned us that they would jail any and all of us if we overstepped our given boundaries. We felt alone and rejected. We were being treated as if we were the wrongdoers, we were the criminals by daring to demand action. I remember thinking that none of this made any sense. We had done nothing more than to ask those whose duty it was to protect our health to perform their duties.

The demonstration had a side effect. It caused further illnesses. Children who were perfectly normal prior to entering the dump started to develop rashes on their faces. Many people, myself included, suffered from severe eye irritation. People were coughing and gagging. Some developed severe headaches and had to leave the dump. The appearance of these illnesses while we were at the dumpsite only served to strengthen our belief that toxic chemicals were buried within the dump.

In an act of final desperation, I and three other women hired an attorney who issued a restraining order against any further work in the dump.

Four days after that order was issued, while we were in court, the city agreed to work with the residents to help solve the problems of Brookfield. They have never lived up to their agreement. In fact, before the day ended, truck traffic and construction was back to normal, and we were faced with the difficult task of trying to raise the money necessary to post a bond in order to enforce our injunction. The city knew that we would not be able to raise the required sum and it just violated our agreement.

By August 1982, almost 8 months after the onslaught of our illnesses, we were still at square 1. Dr. Saul Blumenthal, head of New York City's Bureau of Biostatistics, had examined the mortality rates for our area for the previous 6-year period and had determined that there was no indication of any additional mortality in that time period. Dr. Blumenthal said the odors may be aesthetically unpleasing but they weren't killers. I can only add an amen to Dr. Blumenthal's high-handed remark. It was bad enough that the dump was causing illness. Who needed to have people die.

Dr. Blumenthal's statement, however, represents the attitude typical of our supposedly responsible officials. It seemed that everyone we spoke to wanted a body count before they would do anything.

In his continuing effort to help, Congressman Molinari assigned to his staff the task of performing a health survey among the area residents to try and determine the extent and frequency of our illnesses. The health department, shamed by this action, announced that they would also perform a survey.

Then, during the summer of 1982, we learned that the alleged dumping had, indeed, taken place. That, in fact, anywhere from 3 to 8 million gallons of liquid wastes were sent by a company called Hudson Oil, or Quanta, and were dumped at Brookfield over the 2-year period from 1977 to 1979. I understand that this company is notorious for illegally disposing of toxic wastes.

Also, during the summer, the State of New York rated the level of toxicity of Brookfield and assigned to it a toxicity level of 80 points on a scale of 0 to 100. We again accepted these revelations with mixed feelings. On the one hand the true nature of the Brookfield threat was finally being exposed—on the other hand it was like the voice of doom. I could see my dreams crumbling. My oldest daughter was developing a chronic wheeze, my youngest kept getting sore throats and nose bleeds, and I constantly suffered from dizziness, nausea, and a slight but noticeable loss of equilibrium.

In October 1982, Congressman Molinari presented the preliminary findings of his health survey. The city health department issued their findings that November. Both surveys found that the Brookfield area residents experienced an illness rate twice that of any other area on Staten Island.

Finally, I thought, we have everything necessary to get direct swift action. Brookfield dump has now been shown to contain hundreds of thousands of gallons of toxic waste, the land has been disturbed through construction, and now the health department agrees that people have been getting sick as a result of being exposed to this construction. I truly thought our problems were at last over.

On November 5, 1982, almost a year after our troubles began, we called upon the mayor of New York City to come to Staten Island, examine the evidence his agencies had accumulated, listen to our problems and help us solve them. The mayor refused. He responded to our pleas by saying that he was not going to come to Staten Island to be badgered by Staten Island housewives. He had commissioners to deal with these problems.

Now, almost 18 months have passed. I am exhausted. We have held demonstrations. We have gone to court. We have met with every agency and every official that would meet with us. We have been labeled as hysterical, frustrated housewives by the department of sanitation. The health department wants dead bodies before it will count our complaints as valid. Our illnesses have been branded as hysterical responses based on an overactive imagination.

We need your help. I believe that the illnesses that I and my family suffer from are directly related to the digging of that huge trench in the Brookfield dump. I believe that the opening of this trench released those toxic materials into the air causing the whole community to suffer. And I am convinced that the continued ill health of the entire community is a direct result of the callous disinterest of my local and State officials and the agencies they manage, coupled with their own inability to handle the problem of toxic waste dumping. I think the problem is too big to be handled by the city, or even the State.

Eighteen months is too long to wait for the pittance of help we have received. I don't know how you can get what needs to be done accomplished, but if I could make a request of you, I would ask that you assure me and others who may be in my situation that these never-ending investigations will be shortened. That whenever, as in our case, there exists reasonable evidence that the public's health is being affected, action be taken first and proof positive determined afterwards.

I thank you for your time and patience. I once bought the American dream. It has been snuffed out. I come here today in the hope that you may be able to help me once again to rekindle that dream.

Thank you.

Mr. Levitas. Thank you very much, Mrs. Jones, for that eloquent statement. Given the trail of tears and frustration that you describe, I am surprised that your anger is not even more manifest. Just hearing what you said has gotten me even more angry just to hear the story. And you have lived through it.

Next, I would like to ask Mr. Ranier and Mr. Hollingsworth if they would offer us their contribution this morning. We are very appreciative of your presence here today and look forward to hearing from you.

Mr. Hollingsworth.

TESTIMONY OF JOHN HOLLINGSWORTH, LAKE CHARLES, LA

Mr. HOLLINGSWORTH. Yes; my name is John Hollingsworth. I am from West Lake, LA. I am 23. I have two small children I am trying to raise with no income because of an accident that happened at this BFI landfill site.

I had been working there for 3 years. I started having back trouble, and I was put in a hospital for a few days. They told me I had two broken vertebras. They turned me loose. I went back to work. I worked for a few weeks, and it started—the pains got bad enough where I couldn't work, and I went back to the hospital.

And they put me in—run tests, and I must have went out for awhile. I come to in a few weeks, and they had took part of my back, cut them out because of infection which they don't know what it was. And I stayed in intensive care for 2 months. I was in the hospital for 3 months altogether. And I am trying to raise my family off of nothing. And I received in the mail a bill from the hospital, saying please pay in full, $96,000.

At the time when I became ill they had had a train derailment in Livingston, and this site was receiving all of that chemical there. I never even knew what it was. It was all, the chemicals were all mixed together. I hadn't been ill. I hadn't had a cold of any sort or anything for at least 6 years. And then all of a sudden this came up. And they don't know; the doctors are still calling me.

We have people around in New Orleans that have run biopsies, different tests, and nobody—they just all tell me they don't really know.

I have tried for different incomes, Social Security or so, but I haven't got anything, no information back on that. They paid me 6 months while I was out of—from the time I went and saw my first doctor, they paid me 6 months after that. And I haven't been receiving anything since.

I don't—the chemicals that were taken in there, we don't even—we have never—some of them they came from—they didn't even know, you know. It was just take it. That is the way it is. And so I am hoping that somehow, get something started, because I know it is bound to happen to others, because there is at least 10 of us that did work there that—I imagine 30 all together, but 10 that handled chemicals some times 36 hours at a time, 100 hours a week. That was very easily done. And it would almost cost you your job if you didn't do it.

[The statement of Mr. Hollingsworth follows:]

TESTIMONY OF JOHN KENT HOLLINGSWORTH

My name is John Kent Hollingsworth. I am 23 years old. I am married and have 2 children, one 5 years old and one 19 months old. I graduated from Sulphur High School, Calcasieu Parish, Louisiana in 1977.

I had worked for Browning Ferris Industries for almost 3 years, when in December of 1982, I developed a serious infection around my spine, which was followed by other complications. I was admitted to Lake Charles Memorial Hospital for 3 days in November of 1982. I was readmitted on January 18, 1983 and remained in the hospital for 72 days. I presently am aware of almost $110,000.00 in hospital and medical bills. To my knowledge, none of these bills have been paid.

When I became ill I was working as a tractor operator for the BFI landfill operations at Willow Springs in Calcasieu Parish, Louisiana, and my duties consisted of mixing hazardous wastes with kiln dust and moving the sludge into waste pits. At the time I became ill, to the best of my knowledge, I had been working for several weeks with waste received from the Livingston Parish Illinois Central Gulf Railroad derailment, which involved a large chemical spill and fire.

I weighed 160 pounds at the time I became ill, lost 40 pounds during the illness, and am now back up to 150 pounds. Prior to going to work for Browning Ferris, I had worked for several months for Lone Star Feed Store in Westlake, Louisiana; for about a year at Brimstone Fabricators in Sulphur; and for several months at various plants in the Baton Rouge area. At the time of the illness, I had been working for BFI for almost 3 years.

I was making about $250.00 net per week at the time I became ill.

When I became disabled, I continued to receive reduced salary based on 40 hours a week. I received this from the time I was hospitalized on January 18, 1983, until approximately April 15, 1983. Since that time I have had no income and have relied on savings, which are now exhausted, and the help of friends and family.

I have filed for social security and my claim is pending.

I have had no significant illnesses, diseases or injuries prior to this one, nor does my family have a history of illness or disease in any way similar to this one.

Although I hope to return to work, I have been advised by the doctors to remain off work indefinitely.

I have received no workmen's compensation benefits and none of my hospital, medical or drug bills have been paid.

My local doctor has called in a specialist from New Orleans. We have not yet received her report regarding the connection between my illness and my exposure to hazardous wastes at work.

Mr. LEVITAS. Mr. Drew Ranier.

TESTIMONY OF DREW RANIER

Mr. RAINER. Mr. Chairman, if I could, just briefly, on Mr. Hollingsworth's situation, he was employed as a backhoe operator in Parrishville at BFI landfill. He got very ill, required operation on his spine and 3 months hospitalization. He had numerous complications following initial draining of the abscess. He failed to respond to antibiotic treatment for most of that time until the very end of this stay. The doctors are convinced that there is some immune problem involved here.

The waste that he was dealing with for several weeks prior to becoming ill was, as he said, from the Livingston Parish train derailment. That is an Illinois Central-Gulf derailment involving many different types of chemicals. It may be that in the fire that ensued that the dioxins were created in the burning. We are not sure of that. We are in very early stages of discovery in the case, finding out exactly what we are dealing with.

So we are in a position, or Mr. Hollingsworth is in a position of being very uncertain in terms of medical proof about what has happened to him. But we do know that there was a massive immune breakdown in his case. The situation in terms of compensation support is dire. First of all, the workmen's compensation fund, or funds which would normally be available to someone who becomes ill because of working conditions, has denied coverage on the grounds that there is no certain medical proof at this point that this is even a work-related condition, although we know from the process of elimination that they have no other theories as to why that is so, why he got sick.

So the problem is dire in that normally workmen's compensation carrier or insurance would provide at least for his hospital and living expenses. They have not done that in this case, and they have denied that to date.

On the other hand, the hospitalization insurer has taken the position, we believe, they haven't answered the suit against them yet.

But they will do so shortly; that, in fact, this is work related and they have refused to pay. So there are approximately $110,000 in outstanding medical bills now with the workmen's comp insurer saying on the one hand this is not work related and the hospitalization insurer, on the other hand, saying it is. He is in a limbo, then, of no compensation at all.

Now, there may be other remedies. There may be remedies against the railroad. There may be remedies against his employer in tort other than workman's compensation. That remains to be seen. We are naturally going to explore those. But to the extent my testimony could help the committee, it would be about what the remedies are and what could be done.

As I understand the committee's inquiry about victim compensation, it regards basically remedying bad situations. I would make the following suggestions. First of all, what we need and what will not cost the Government a dime or the Superfund a dime are increased remedies. For instance, we protect people in society. An example I can think of, because I tried a case like this last week in New Orleans, we protect seamen. Under the Jones Act of 1920 we provide them with very special remedies. There are no such remedies for people who are victims of hazardous wastes, whether they work there or they live next to them, or otherwise.

The standards of proof in almost every State are the same as they are for every other litigant. It is easier for a seaman to recover from injuries than it is for a John Hollingsworth, or someone who lives next door to a site. So without even spending a dime from the Superfund, the problem can be addressed.

The way it can be addressed, very simply, is by reducing the burdens of proof that are put on these people to show that there is a relationship between their injury and their working conditions or their living conditions. There is a very simple way to do that. Require only that they show that they were exposed to significant levels of toxic chemicals, and then let the burden shift to the disposer or the producer of the chemical to then prove that in fact the illness is not related to their exposure rather than doing the way it is done now, and the disposers and producers say simply, proof that it is related.

And the problem is that that is very, very difficult proof and the companies, disposers or producers would be in a much, much better position to know exactly what was there, exactly what the people were exposed to. And in the case of Mr. Hollingsworth they certainly should be medically concerned about one of their own employees. So why not put the burden on the producers and disposers when it comes to medical proof?

The other problem brought up by Mrs. Jones, of course, is that the cost of these things is phenomenal. For an injunction you have got to put up a bond, so an injunction is almost meaningless because to shut down a profitable hazardous waste disposal site would be interrupting profits that may be in the region of hundreds of thousands of dollars per week and the bond would have to cover that potential loss. So it is literally impossible to obtain injunctions.

With regard to keeping medical burden of proof on the people who are injured, they have to spend conservatively, to prove their case in court by a preponderance of the evidence that their chemical exposures caused their injuries, at least $10,000, and as high as $50,000. We are talking about medical testimony that costs $350 an hour to obtain. So as long as the burden remains on the injured individual to establish the connection, the cost of litigation is exorbitant. And only the most, most serious of cases can afford to be litigated.

I think that the Superfund may be of some help in this regard in the temporary or short term. That it could provide compensation with subrogation rights. And by that I mean that the Superfund could provide temporary living expenses in the place of workmen's compensation and that that would be recoverable if and when recovery was made against some third party, the person actually responsible and at fault for the exposure.

I think it would be a lot better for this country if the people who are actually at fault for creating the problems have to pay, rather than a Government mandated insurance program. And one of the main reasons for my belief of that is that you can't actuarially make these places safe. The only way to make them safe is by making the people who are responsible for the unsafety pay for them. To the extent that those people are gone or no longer exist, the Superfund is there. It should be there as a backup. It ought to be there for temporary help. But the fact is that the people at fault for causing the problems are the ones who should pay, not the taxpayers and not some federally mandated scheme.

That is the best, the most efficient, the most direct way of solving this problem. And the best way to do that is to make a very simple change in the law. And that is treat people who are injured, who are exposed, differently than you treat other people in court. And you do that by reducing their burdens of proof. It would be a very simple way of doing it.

Mr. Hollingsworth's remedies in this case, he faces almost insurmountable medical proof problems when you have to go into court and prove by a preponderance of the evidence that what has happened to you is related to this specific exposure. It is a mountain to climb. It is a mountain to climb, evidence-wise. You have got to bring in experts that are not available in Lake Charles, LA.

He has good treating physicians but they are not trained toxicologists, they are not trained in hazardous waste exposures. They have got to go outside the community. They have got to go to the major medical areas, the few areas where you can find that kind of expert testimony. That testimony does not come cheap at all. So the evidentiary problems as they presently exist for Mr. Hollingsworth or anyone else in this room who has hazardous illnesses are almost insurmountable without change in the present law. And that change can be made without great expense to the Superfund.

I would suggest the Superfund remain there for what it is, and that is a backup when we can't find financially responsible parties and when we need it for temporary purposes. And then allow the fund itself to recover if and when we can establish fault.

Thank you, Mr. Chairman.

[The statement of Mr. Ranier follows:]

TESTIMONY OF DREW RANIER

My name is Drew Ranier. I am a lawyer practicing in Calcasieu Parish, Louisiana. I represent John Kent Hollingsworth in connection with a severe illness he incurred while employed by Browning Ferris Industries at the Willow Springs hazardous waste landfill disposal site.

A claim for workmen's compensation benefits was filed on April 8, 1983. The statutory weekly benefit and hospital and medical expenses have not been paid to date. The weekly benefit would be approximately $200.00.

Consequently, demand was made on the group health insurer, Provident Life & Accident Insurance Company, to pay hospital and medical expenses which are approximately $110,000.00. These hospital and medical charges were not paid as of July 5, 1983, and suit was filed accordingly. Presumably, the hospitalization insurer takes the position that the illness is work-related.

Also, on June 30, 1983, suit was filed in tort against the employer, Browning Ferris Industries, alleging intentional acts by the employer which caused Mr. Hollingworth's illnesses. These allegations primarily concern failure to provide adequate safety at the waste disposal site. If Mr. Hollingsworth can prove that these acts were intentional, rather than negligent, then he may be able to recover his full loss of wages, hospital and medical expenses, and items of general damages under Louisiana law such as physical and emotional pain and suffering. I do not want to comment on specific work practices by BFI because those practices are being litigated in the tort action. However, we can say that it is our belief that they were hopelessly inadequate.

In general, there are adequate remedies under Louisiana law for compensation of Mr. Hollingsworth. There are, however, two problems worth discussing:

(1) The cost of obtaining competent medical evidence on the relationship between toxic wastes and illness; and

(2) The living expenses of the injured party and his dependents during the lengthy period of time when evidence is being gathered and prepared for trial.

I would not propose a modification of the remedies available to Mr. Hollingsworth. However, I would be in favor of providing some type of temporary living allowance from available funds with subrogation rights against prospectively liable defendants. I would also be in favor of increased education and training of the medical profession, so that the treating physicians in communities with significant hazardous waste activities can develop expertise in treatment and analysis of toxic waste related illnesses, making it unnecessary for litigants to obtain distant and expensive medical testimony regarding the relationship between toxic waste and illness. In Mr. Hollingsworth's case, we are confident that it will require tens of thousands of dollars in medical and related expenses to prepare and try the matter.

Mr. LEVITAS. Thank you very much, Mr. Hollingsworth and Mr. Ranier, for your contribution. I have some questions, and I would imagine that the other members of the subcommittee do as well, that we will now present.

Before I do so I am informed there are representatives of Browning Ferris Industries present, and note that at this time in the interest of objectivity that we will afford them an opportunity to comment for the record on your statements if they so desire, because we are really trying to develop as objective and balanced an approach to this matter as we can.

Let me just take this opportunity to make this observation, not in any way in responding to the types of situations which the witnesses today have presented but just because it is a fact. For almost 100 years now—certainly for 50 to 75 years—we have lived in a society that has improved its quality of life and benefited from the scientific and industrial base of this country, and from the chemical products that have been developed to bring about lower costs, convenience, and industrial progress in our society.

At the time when these developments, in some instances—I guess even in most instances—were coming along and these chemicals were being used and developed and disposed of, they were for the most part being handled in accordance with the state of the art at that time, and what was then known. And now, in the last number of years, we are beginning to pay a price for that. We are finding out new information about these products and their consequences, and we are finding hazardous waste dumps that, in some instances, are 20, 30, 40, even 50 years old, and causing problems.

So what the Superfund Program was designed to do and what our concerns are is how do we deal with this? In some instances--and, again, I would suggest in most instances—the people who created these sites at the time and handled the chemicals at the time were doing what either they thought was correct or, in some instances, were actually doing what the Government told them to do.

On the other hand, we do know in recent years there have been extremely serious examples of the illegal dumping of the sort that Mrs. Jones described, that we have heard of from other sources. But while we do need to focus our attention on holding those people at fault who are at fault, we have a question which transcends that, and that is: What do we do about the problem? What do we do as a nation, as a society?

There is a shared social responsibility here that we simply cannot ignore, that is not going to go away, and I suggest that as our science improves we are going to find out that there are additional problems we don't even know about yet. By the same token, there are going to be additional chemicals, products that will be developed for the purpose of making a better life, whether it is in plastics or pesticides or pharmaceuticals or insulating materials or the like.

So while there is no doubt in many areas blame to be assessed, and individuals specifically to be held responsible, both civilly and criminally, in some instances, there is even a broader question, and that is: How do we deal with this enormous problem that Congressman Gephardt identified earlier, both for the resources of our Nation, and, to me, more importantly, for the human beings who have suffered who are clearly innocent parties?

I just make that observation because I think we need to put it in context.

Now, Mr. Payne, Mrs. Payne, you mentioned in the course of your testimony that on several occasions you have been seen or treated or examined by physicians from the National Center for Disease Control. I was wondering how you first got involved with CDC.

How did you happen to come to them, or they to you?

Mrs. PAYNE. When they found out that the dirt was contaminated, the St. Joseph Hospital set up a clinic for us to go over there and have tests made; anyone that lived around or close to the contaminated dirt, that we definitely should have tests run.

Mr. LEVITAS. And so it was through the St. Joseph Hospital?

Mrs. PAYNE. Yes.

Mr. LEVITAS. And the notoriety that surrounded the identification of this dump that you got into the CDC?

Mrs. PAYNE. Yes.

Mr. LEVITAS. What is the status of the Minker-Stout site? It is a closed site, I take it, now. Has it been cleaned up?

Mr. PAYNE. No, sir.

Mrs. **Payne**. I haven't seen anything they have done. Where the dirt was dumped, there are no signs. There is no fence. There is nothing at all.

Mr. **Molinari**. Would the chairman yield for a moment?

Mr. **Levitas**. I would be happy to yield.

Mr. **Molinari**. Mrs. Payne, do I understand that you have a sketch or diagram there showing the layout of the houses and your prior house?

Mrs. **Payne**. Yes.

Mr. **Molinari**. Do you have copies of that?

Mr. **Payne**. We have a few, yes.

Mr. **Levitas**. While we are getting copies of that, let me state that, without objection, that the complete statements, written statements, of all of the witnesses will be made part of the record at the appropriate place.

Mr. **Molinari**. Mr. Chairman, if I could continue with two questions on that score?

Mr. **Levitas**. Go right ahead.

Mr. **Molinari**. The Minker site is almost diagonally across the street from your prior home; isn't that correct?

Mrs. **Payne**. Yes.

Mr. **Payne**. Yes.

Mr. **Molinari**. If I understand this diagram right, we find homes behind your home, or down the road, to where Abrahamson lived, Henderson and Webb. They would be compensated in the Federal buyout program, but—no, I am sorry; the homes included are on the other side of the street, away from Minker.

The point I am trying to establish is, it is my understanding that although your home is directly across the street from the Minker site, you were not eligible for a buyout. Yet, others on the other side much further removed from the actual site, the Minker site, were included in the buyout program. Is that correct?

Mrs. **Payne**. That is right.

Mr. **Payne**. That is correct.

Mr. **Molinari**. Did anybody ever give you a reason for that?

Mrs. **Payne**. The road was the cutoff.

Mr. **Molinari**. The road was determined arbitrarily.

Mr. Wessel, do you have anything you could add?

Mr. **Wessel**. The Center for Disease Control indicated that unless there is dioxin on your property at a level of 1 part per billion or more, you will get no relocation assistance. They recommended that to EPA and FEMA concurred with that. The families across the street did not have any measurable dioxin. They are still being tested at this time. But they have not had any kind of relocation assistance extended to them because of that reason.

Mr. **Molinari**. But everyone that was included in the buyout did have levels that exceeded that figure?

Mr. **Wessel**. One part per billion or more, yes.

Mr. **Molinari**. Thank you.

Mr. **Levitas**. Mrs. Payne, in visiting the physicians, as you have described, did you ever discuss with them the possibility of dioxin as being a cause of some of these problems? And, if so, what response did you get?

Mrs. **Payne**. Not until after I found out dioxin was there. I have talked to my doctors several times and they don't have an answer.

Mr. **Levitas**. They have never said one way or the other as far as the possibility of dioxin being the cause?

Mrs. **Payne**. No; they said they don't know.

Mr. **Levitas**. Just for the record, you have described the many serious problems which your family has suffered, health problems. Could you just tell us if either you or your husband's family have a history of that type of medical problem which you related today?

Mrs. **Payne**. No; on both sides, our families are fine.

Mr. **Levitas**. I am sure you are not fully capable, Mr. Wessel, of answering this question, but CDC, of course, doesn't make actual decisions as to how these sites would be handled. But it just seems to me totally arbitrary looking at this chart to have eliminated Payne and included Pierson or Vickers.

Mr. **Wessel**. Well, if you look at the Pierson property, there is dioxin on their property even though it is not directly adjacent to their house. On the Pierson and Lynch property—I believe there was the chance of migration at that time. I don't think that CDC believes there is the chance of migration across the street. If you look at the Korenak house, however, they have dioxin on their property in that small corner. If you look at the distance between the Korenak family and dioxin contamination in relation to that of the Paynes to the dioxin contamination, the Paynes would have lived closer so you would expect that they should have received some kind of assistance, also.

Mr. **Levitas**. Without objection, the diagram of the vicinity of the Minker dioxin site will be made part of the record.

Mr. LEVITAS. Mrs. Jones, have you ever been able to ascertain what chemicals and substances were illegally dumped in that——

Mrs. JONES. It has been told there is a pool of cyanide and arsenic; we have been told there is toluene, benzene. We have seen no reports that show there is any high level of these toxics that are supposedly in there. We have been to meetings, Subcommittee on Crime in Manhattan, where two gentlemen testified that they dumped it.

Mr. LEVITAS. Did they say what the source of this material was, where they got it?

Mrs. JONES. One was the Quanta that I mentioned in my testimony, and there were other companies involved, also.

Mr. LEVITAS. We heard from the people who formerly lived in Times Beach that when news of the dioxin problem got around, there were not only fears and concerns that the people directly affected felt amongst themselves, which you described occurred in your neighborhood, but they also talked about the sort of reaction of people who didn't live in that area, treating them almost as pariahs, as lepers.

Mrs. JONES. That is true.

Mr. LEVITAS. Did you have any experience of that sort in your area?

Mrs. JONES. People that came to the neighborhood that were looking to buy homes stayed away from the neighborhood. People that put their houses up for sale, they sold, but they lost a lot of money. People that had binders on the house, the minute they mentioned stay away from Brookfield, they lost their binders. We were lepers. We are still considered that way.

Mr. LEVITAS. The next question I would like to put to Mr. Hollingsworth.

Before the time you dealt with this material before the train accident, were you in generally good health?

Mr. HOLLINGSWORTH. For 6 years, I know I hadn't missed a day of work because of illness. When it happened, I worked for at least 3 weeks, staying up all night with the pain and putting up with it during the day to hold my job. And they are the ones that told me to go get it checked, to go to the hospital. And they kind of left me alone.

Mr. LEVITAS. Have any of the other people who worked or lived near the BFI site, that you are aware of, experienced any illnesses of the sorts that you described?

Mr. HOLLINGSWORTH. Well, it has been a while since I have even been around there. But my dad lives down the road. They buy their water because you can't even take a shower. It really smells. They haven't had tests run that would tell them what really was in it. But the people that worked there I haven't seen since I have been in the hospital.

Mr. LEVITAS. Before you started doing work on cleaning up this material from the train wreck, did your employer give you any information about the type of materials you were going to be working with or any warning as to whether or not they were hazardous, and did they provide you with any special type of protective clothing and equipment? And, if so, did you use it?

Mr. **Hollingsworth**. We had masks, rubber boots, and things like that to handle it with. But late in the night when you were just about the only one there and these trucks constantly 24 hours a day hauling this stuff, if you got some inside your boot, or the masks would only last so long—well, you were more or less without. When I first went there, there were pits that had been there for years, and we had nothing whatsoever to wear, no masks. We mixed these pits until they were solid just to cap them over so they wouldn't be open to the air.

Mr. **Levitas**. Was a biopsy done on the growth after your surgery?

Mr. **Hollingsworth**. Right before I was let out of the intensive care, I had fat where they could find it removed and blood and different things. And I have been back once because they claimed they just let the blood spoil or something. They were not in that big a hurry. And of what they came out of my back, it was infections is all I know. That is all I have heard. While I was in there a few times, I swole up the size of the bed. And a couple times they punctured my chest, at least nine times, to put tubes in my lungs, and couldn't give me pain medicine, you know. They gave me very little so I wouldn't get where I needed it. They would just throw a towel over my face, poke a hole and do what they had to do. Wasn't very——

Mr. **Levitas**. You said that you are married and have two children?

Mr. **Hollingsworth**. Yes.

Mr. **Levitas**. Did they suffer any health problems during the time that you were working at the landfill?

Mr. **Hollingsworth**. My wife had a miscarriage. She lost lots and lots of blood. But, luckily, it hasn't shown up in my kids or anything.

Mr. **Levitas**. One final question about the equipment you said you were furnished. You said you had boots and masks. What type of masks were you provided?

Mr. **Hollingsworth**. The masks were organic masks.

Mr. **Levitas**. Did it cover your whole face?

Mr. **Hollingsworth**. You could get—they give you a choice. They didn't tell you what to wear, but they give you the mask. You had a full face, which didn't cover your hair, and that was just as easy to get it through your hair as it was by putting it on you. You worked in it whether you had it or not.

Mr. **Levitas**. One question to you, Mr. Ranier: I gather from your description of what you understand the law to be in Louisiana, the burden of proof is on the plaintiff and there is no doctrine of absolute liability in the case of toxic chemical——

Mr. **Ranier**. That is generally correct. Now there are strict liability doctrines for dangerous substances in Louisiana. But that doesn't apply. You still have the burden of proof of your case medically. In other words, you could prove you were exposed, you can prove you were entitled to recovery because of the exposure, but you still have to preponderate; that is, you have to have the medical doctors come in and say as a matter of reasonable medical probability this condition is caused by that.

Everywhere that I know of in the country that has strict liability doctrines, the strict liability does not extend to the medical proof. That is the real problem in these cases. It is not the problem of proving they were exposed; it is a problem of proving what caused it, how it caused it and getting the doctors to come in and say it is a matter of medical probability that it did.

Mr. LEVITAS. Yes. And, in fact, in some instances, in fact, many instances, in the case of exposure to toxic chemicals, the particular condition may not manifest itself for literally years after exposure to the condition. And you have got all sorts of questions—statute of limitations, finding the people—all manner of questions which we are going to be addressing in our further hearings, and particularly tomorrow where I expect to have some extremely useful testimony on both sides of this issue.

Mr. Molinari?

Mr. MOLINARI. Mrs. Payne, I think it was in your testimony you made reference to the fact that you had a letter from the State Department of Health indicating that dioxin may have been the cause of your medical problems.

Mrs. PAYNE. Yes.

Mr. MOLINARI. Do you have a copy of that with you?

Would somebody bring a copy of that up, please?

Mr. Chairman, I would like to ask that this letter of the Missouri Department of Social Services, Division of Health, dated May 11, 1983, addressed to Representative Richard A. Gephardt, be introduced as an exhibit and made part of the record of this hearing.

Mr. LEVITAS. Without objection, it is so ordered.

[The letter referred to follows:]

MISSOURI DEPARTMENT OF SOCIAL SERVICE,
DIVISION OF HEALTH,
Jefferson City, May 11, 1983.

Representative RICHARD A. GEPHARDT,
St. Louis District Office, St. Louis, MO.

DEAR REPRESENTATIVE GEPHARDT: The Ronald Payne family is included in both the health interview, and the physical examination and laboratory aspects, for the current Missouri dioxin investigation. Families in whom there were findings among the physical examinations or initial laboratory data were notified of these findings in April. We anticipate that it will be a matter of several weeks before all of the remaining test data are available for review by the medical panel. At that time, Mrs. Payne's letter will be reviewed by the panel along with other available data.

In the meantime, it appears to me that some of the symptoms reported by Mrs. Payne could be classed as compatible with reported health effects of dioxin. These include hemmorrhagic cystitis, "nerves", "repeated sore throats and colds", and various rashes.

It must be emphasized that while these symptoms may be so classified it remains to be determined whether they are or are not actually related to dioxin. They are all somewhat nonspecific—i.e. there are other factors which could be responsible, they are also somewhat vague and would have to be more completely documented before determination could be made with greater degree of assurance.

Since extensive EPA testing has failed to confirm the presence of dioxin in the former Payne premises now occupied by the Davis family, it remains unclear how, if at all, the various family members would have been actually exposed to dioxin at levels sufficiently high to cause the health problems reported in Mrs. Payne's letter of April 14.

Thank you for your concern.

Sincerely,

H. DENNY DONNELL, Jr., M.D., M.P.H.,
Director, Section of Disease Prevention.

Mr. **Molinari**. Thank you.

Mr. **Levitas**. Also, I believe, Mrs. Payne, you said you had your hospital records, medical records, available. I would request that they be made available to the subcommittee staff. I will not make them part of the record, but I would like to have them for our examination.

Mrs. **Payne**. I have some of them. I didn't have a chance to get all of our records.

Mr. **Levitas**. Thank you.

Mr. **Molinari**. Mrs. Payne, the letter was dated May 11. I notice in the first paragraph it says: "We anticipate that it will be a matter of several weeks before all of the remaining test data are available for review by the medical panel."

Mr. Payne, Mrs. Payne, Mr. Wessel, does anybody know whether those tests were concluded and what information is available?

Mr. **Wessel**. The raw data was received by the Center for Disease Control in Atlanta and has been shared with the State of Missouri. They have not interpreted the data yet. They expect to release that some time late August, early September.

They had two phases, I guess you could call it, of the health data. Early on, they had a group of 130 residents who were tested, 112 of whom were listed as having abnormal symptoms. Those included such things as anemia, et cetera. The most important tests for liver disfunction and immune system and to detect soft tissue sarcoma, those are in-depth tests and will be forthcoming at the end of August, we think.

Mr. **Molinari**. Now, let's then turn to the second paragraph, if we can. In the second paragraph, for the sake of those in the room, and for the sake of the record, Dr. Donnell, Director of the Section of Disease Prevention, mentions:

> "* * * it appears to me that some of the symptoms reported by Mrs. Payne could be classed as compatible with reported health effects of dioxin. These include hemmorrhagic cystitis, 'nerves,' repeated sore throats and colds, and various rashes."

Mrs. Payne, we have heard from your testimony that you and your family have suffered from some of these symptoms. Could you tell us whether these health effects described by the doctor were observed in the neighborhood in other residents, as well, or to what extent?

Mrs. **Payne**. Just about all of my neighborhood have had the same complaints, health problems, as we have.

Mr. **Molinari**. These symptoms that are being described here?

Mrs. **Payne**. Yes. Their children and——

Mr. **Molinari**. I do want to incorporate for the record a caveat: Dr. Donnell's letter, referring to the symptoms, states "while they may be so classified, it remains to be determined whether they are or are not actually related to dioxin." Nevertheless, we are seeing throughout these hearings, and any time we have been to a site, the same kinds of complaints.

I think our observations tell us something. You start to draw a picture when you see these symptoms and read of them.

I turn to Rita Jones. Rita, nerves is one symptom that medical experts say could be related to dioxin. I suggest that they may be related to other toxins, as well. Have there been suggestions that you and others, are suffering nothing more than nervous problems?

Ms. JONES. Yes.

Mr. MOLINARI. A nervous problem?

Ms. JONES. Yes, there have been. It seems there is a lot of people in my area, we are all suffering from the same thing, nervousness. We are all breaking out with two similar rashes, and when we do break out, it is a lot of people at once.

There are two different types of rashes, only two. One is an acne type of rash that is mostly in adults, and children come down with a rash that looks like ringworm, and the doctors usually in the area prescribe medication, hydrocortizone, I believe it is, in a cream base, and they use it for 4 to 6 weeks, and the rash will clear up and it comes back again.

Can we all be suffering from nerves?

Mr. MOLINARI. Rash is one of the more common symptoms of people exposed to toxic chemicals and hazardous substances. Do you know people in the neighborhood who go away on vacation for maybe an extended period of time? What happens to them while they are away?

Ms. JONES. I, myself, my family included, we have been away to Washington. We went from Washington. We weren't home more than hours and my husband started with severe nosebleeds again. My little one was complaining about a sore throat again. My big one was wheezing all over again.

We had to start medication again.

Mr. MOLINARI. I take it what you are saying is when you are away, these symptoms disappear?

Ms. JONES. There were no symptoms whatsoever. I didn't have to administer any medication for 4 days or 4 nights to either child.

Mr. MOLINARI. How long after you leave the area going on vacation do you notice that the symptoms disappear?

Ms. JONES. A few hours later.

Mr. MOLINARI. That quickly?

I would like to turn to Mr. Ranier.

Mr. Ranier, I have been interested—I am an attorney myself—in your testimony. I think you have touched on some of the serious problems that people afflicted with the conditions that we are discussing today have when they go to a lawyer. Have you tried cases of toxic exposure, or problems associated with it, before?

Mr. RANIER. Yes, sir, I have.

Mr. MOLINARI. How do you make a determination? I heard you say—in fact, I think you used the term "insurmountable." How do you make a determination? Do you take these on a contingent fee basis?

Mr. RANIER. That is correct.

Mr. MOLINARI. I assume that would be the only way.

Mr. RANIER. Yes, sir.

Mr. MOLINARI. How do you make a determination, then, to take a case? What factors go into determining whether you will handle a case or not, since it is going to take a tremendous amount of your time? I would assume you would have to have some reasonable expectation of success before you would take on a matter such as this.

Mr. RANIER. Probably the principal controlling factor is the magnitude of the injury. That is, you just can't afford to devote the kind of time and money and effort on a contingency basis that you have to with one of these cases unless you know that you have got a very serious injury and the prospect of recovery is going to be substantial enough to compensate you for your work and for the amount of expense.

I think it is true in almost every State that, technically speaking, the expenses of litigation are the client's responsibility, but in fact, someone in Mr. Hollingsworth's position, who already has $110,000 in unpaid medical bills and has been out of work since January, and has no immediate prospect of returning to work, they are not going to be able to afford those.

So the basic answer to your question is, one, that you have to believe that eventually the medical test is going to show that there is a connection and, second, that the risk you take is at least for a severe enough case that it is going to justify your involvement.

Mr. MOLINARI. In the State of Louisiana, would you have a class action possibility if you had an area such as some of the areas described where there are substantial numbers of people affected?

Mr. RANIER. Yes, you do.

Mr. MOLINARI. I have no further questions, Mr. Chairman. I would just like to wrap up by making the observation that I have been rather sickened by what I have heard today, not that it is anything new. But we have people from three different parts of the country testifying here today, and we can see not only the physical pain in their eyes, but the mental pain that they have exhibited. It places a very heavy burden upon us, because they are crying out for help, it is obvious. We would like to help, and I think that some of the suggestions that you have made, Mr. Ranier, and those of the other, witnesses are going to be seriously considered by the subcommittee.

And for the rest of you, I just want to express my own deepest appreciation.

Mrs. Payne, your first airplane trip—that has to be an experience to do that to come here. You deserve our attention—not only our attention, but our action, and I hope that we can play some role in addressing the problem properly so that we can offer some assistance to others like yourself. Rita, I appreciate your coming, as well as you, Mr. Hollingsworth, with a horror story that has us all shocked.

Thank you.

Mr. LEVITAS. Congressman Breaux.

Mr. BREAUX. My time is very brief.

Mr. Ranier, is the landfill still open at Willow Springs?

Mr. RANIER. It is, and the Environmental Control Commission of Louisiana, I believe, has issued a closure order for December of this year.

However, that has been appealed by BFI. I think that is the present status of the operation.

Mr. BREAUX. There are a lot of examples with regard to common law cases that have been developed over the past that provided compensation for plaintiffs who have been exposed to chemical toxic waste areas.

Mr. **Ranier**. There are traditional theories of recovery. They are still burdened with the problem of proving that the plaintiffs undertaking—and they are available to people. The problem with an employee, of course, his rights against his employer, Mr. Hollingsworth against the employer, are severely curtailed even to begin with, and directed into worker's compensation in general.

There are some exceptions to that. But the workmen's compensation remedy in this case has been meaningless to date. No workmen's compensation has been made. They voluntarily kept him on salary up to a period of several months of his going into the hospital, but the problem he was faced with then was he had to decide under the Louisiana law within 6 months whether to make a claim.

As soon as he made the claim, the volunteer payments stopped. He has been without compensation now since the middle of April, which is the time that the claim had to be made to ensure that he did not lose all of his rights in the future.

The 6 months did not run and voluntary payments could stop and there would be no legal remedy, so there are remedies, they are restricted even in worker's compensation, you still have the same burden of connecting the working environment with the injury.

Mr. **Breaux**. I think what this panel has shown to us, Mr. Chairman, is that we really are talking about a new area of the law, that the old rules of standards and burdens of proof are going to be impossible for plaintiffs to ever get any resources.

We are in the ironic situation, as staff pointed out to me, if you have a pine tree in your front yard, you could get compensated if the tree died, out of the Superfund. Because you are a human being with hundreds of thousands of dollars of suffering, the law doesn't cover you, and there has to be something wrong with that type of setup that needs congressional attention and congressional direction.

I would say to all of you, I think that by your testimony you perhaps made it a lot easier for those who are going to follow you and for future generations, and we thank you very much for your appearance.

Mr. **Levitas**. Thank you, Mr. Breaux, for those observations.

The subcommittee will stand in recess for 10 minutes, and then I think we will be able to conclude very shortly thereafter.

[Recess.]

Mr. **Levitas**. The subcommittee will please come to order.

I have been advised that one of the ironies of some of these things that keep cropping up is that to the extent that the problems in Ms. Jones' neighborhood, Staten Island, were caused or triggered by the digging of that large trench, which we saw on the photographs that were provided us, that the reason the trench was dug was to allow for the construction of a sewer line required by a sewage treatment project which was funded by the United States Environmental Protection Agency Construction Grant Program, in response to the Clean Water Act, and I just find that to be a very ironic development in this matter.

I want to express, again, my gratitude to all of you for being here today. I don't think you have any idea the importance of your testimony. It is testimony that certainly gives substance to the concerns that many people have, and the type of information you have provided is similar to that we heard on other occasions.

I remember earlier this year having testimony from people who lived in a part of Dallas, TX which was contaminated by lead and what was happening in those communities and the type of physical and emotional response problems that the people had in that area is quite similar to what you have described today, and as Congressman Molinari said earlier, we are concerned, we want to help, and we want to do it in a responsible way, and that is why we must pursue these investigations and hear from all parties, not just from some, and we will do that, and when we are through, to the extent it is possible to know what to do, we will know it.

You have made certainly a great addition to our knowledge as we pursue that.

Mr. Molinari, do you have something?

Mr. MOLINARI. I just have two remaining questions I would like to address to Mr. Hollingsworth, if I may.

Mr. Hollingsworth, in your testimony, you say you were advised—Mr. Ranier, if you have any objection to the questions, please interrupt me—advised by doctors to remain off work indefinitely.

Do you know what prognosis they have for your condition?

Mr. HOLLINGSWORTH. That is what the biopsy is for, whatever they find out what it is, then I will know.

Mr. MOLINARI. Other than the biopsy and any other indication of what your future health problems may be, assuming that the biopsy is negative, any further prognosis on where you are going, healthwise, that is?

Mr. HOLLINGSWORTH. What little bit I can do is pretty painful, so I wouldn't know.

Mr. MOLINARI. There is no indication at this time as to when you will be able to resume working?

Mr. HOLLINGSWORTH. No, none.

Mr. MOLINARI. I have no further questions. I thank you for your patience. Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you very much.

Again, we are grateful and you will have helped countless thousands of other people as a result of what you have done today at great personal sacrifice to yourselves. Thank you. You are excused.

Tomorrow, the hearings will resume on this portion of our oversight and we will hear from Dr. Bertram W. Carnow, director of Occupational and Environmental Medicine of the University of Illinois at the Medical Center in Chicago.

He is an epidemiologist, toxicolist and author of numerous publications on health effects of hazardous waste materials. He will be joined on a panel by Dr. Bruce W. Karrh, who is the general director, medical safety and fire protection, of DuPont Industries. And also Mr. Courtney Riordon, Acting Assistant Administrator for Research and Development of the U.S. Environmental Protection Agency.

It is also possible that on tomorrow's panel they will be joined by representatives of the American Medical Association. The American Medical Association, at a meeting held of its House of Delegates in Chicago last month, adopted a resolution with respect to the subject of dioxin.

A headline which caught my attention appeared in The Washington Post of June 23 of this year which says, "AMA Votes to Fight Dioxin Witchhunt," and article proceeds to say, "The American Medical Association accused the news media yesterday of conducting a witchhunt against the toxic chemical dioxin and decided to mount a public relations campaign to counter the hysteria."

And, obviously, that is a rather interesting position. Given the prestige of the American Medical Association, I feel it is not only appropriate but essential that we hear from them to get their insight to this matter now that they have gone on record concerning this issue.

Mr. Molinari. I just wanted to mention that a day or two later there was a backpeddling on the part of AMA I don't know if you have copies of those follow-up articles indicating that they had some second thoughts about the earlier statements, which I think were drafted by an ophthalmologist.

I don't know how that qualified him to pass upon dioxin. But my recollection is that 1 or 2 days thereafter, the AMA put out a further statement recanting their position and taking a less harsh position on the so-called witchhunt.

Mr. Levitas. Well, I am just really interested to find out what their position is. As the organized representative of the medical community in this country, their position should be known, whatever it is at this point. I would like to know what it is.

I would also indicate that the subsequent hearing we are going to be dealing with in this portion of the victim compensation risk assessment may, as a result of the testimony tomorrow, include other witnesses next week or at a subsequent occasion. We also are considering a much closer look at a parallel and what we can learn from the Italy incident that was referred to earlier today by the witnesses from Times Beach. I have asked the staff to look into that, to find out how we can get a better understanding of what happened there. It is one of the most notorious examples of major contamination as a result of dioxin. As many as 37,000 people were exposed to dioxin as a result of a fire and explosion in that incident.

Is there any further business to come before the subcommittee today? If not, the subcommittee stands in recess until 10 a.m. tomorrow morning.

[Whereupon, at 2:15 p.m., the subcommittee recessed, to reconvene at 10 a.m., Thursday, July 21, 1983.]

[Subsequent to the hearing, the following was received for the record:]

Browning-Ferris Industries,
Houston, TX, August 4, 1983.

Re hearings on hazardous waste victims compensation.

Hon. Elliott H. Levitas,
Chairman, Subcommittee on Investigations and Oversight, Committee on Public Works and Transportation, U.S. House of Representatives, Washington, DC.

Dear Mr. Chairman: On July 20th, testimony was presented to the Subcommittee by Mr. John Hollingsworth, of Lake Charles, Louisiana and Mr. Drew Ranier, Esquire, of Baggett, McCaull and Ranier, Lake Charles, Louisiana with reference to a chemical waste disposal facility operated by Browning-Ferris Industries Chemical Services, Inc., in Willow Springs, Louisiana.

Please find attached a statement in behalf of Browning-Ferris Industries Chemical Services, Inc. for inclusion into the hearing record.

We appreciate the opportunity to present this information to the Subcommittee.

Sincerely,

JAMES R. GRECO,
Division Vice President, Government and Industry Affairs.

WRITTEN TESTIMONY ON BEHALF OF BROWNING-FERRIS INDUSTRIES CHEMICAL SERVICES, INC.

On July 20th, testimony was presented by Mr. John Hollingsworth, Lake Charles, Louisiana and Mr. Drew Ranier, Esquire, Baggett, McCaull and Ranier, Lake Charles, Louisiana with reference to a chemical waste disposal facility operated by Browning-Ferris Industries Chemical Services, Inc. (BFICSI), in Willow Springs, Louisiana. Since a number of lawsuits have been filed on behalf of Mr. Hollingsworth, it is not appropriate at this time to discuss in detail the merits of issues that will ultimately have to be decided by a judge or jury. In order to complete the record before this Subcommittee, however, there are two points which need to be made.

First, BFICSI has an extensive Occupational Medicine Program. The key elements of this program include pre-employment and periodic health examinations; periodic medical surveillance to provide early detection of exposures to chemical, biological or physical hazards; consultation with area physicians concerning the diagnosis and treatment of occupational health exposures; periodic medical inspections of the workplace to evaluate the adequacy of first aid and emergency medical procedures; and periodic meetings with location personnel to discuss chemical exposure. The BFICSI Occupational Medicine Program is under the direction of a consultant, Dr. D. Jack Kilian, who has had 30 years experience in the chemical industry and is currently Professor of Occupational Medicine, University of Texas Health Sciences Center, School of Public Health, Houston, Texas.

Although Mr. Hollingsworth's condition was not considered to be work-related, at the request of BFICSI management personnel at the Willow Springs location, Dr. Kilian contacted Mr. Hollingsworth's treating physicians in early February of 1983. Dr. Kilian's involvement included the release of BFICSI medical history on Mr. Hollingsworth and medical consultation. Dr. Kilian also recommended testing procedures needed to determine potential chemical sources of the infections and it was agreed that BFICSI would pay for this testing. Dr. Kilian's assistance continue until suits were filed in April of 1983.

Secondly, BFICSI provides statutory Workers' Compensation benefits for job-related injury and illness and group health benefits for non-occupational injury and illness. Mr. Hollingsworth's initial position prior to April of 1983 was that his condition was not job-related. Medical bills were paid as provided under BFICSI medical plan and his salary was voluntarily continued. In April, a lawsuit was filed and a new claim form submitted contending Mr. Hollingsworth's condition was job-related. At that time, group benefit payments were continued for the initial condition, coverage was denied as it related to the condition contended to be job-related, and Mr. Hollingsworth's salary was discontinued.

In view of Mr. Hollingsworth's inconsistent positions, efforts were initiated through Dr. Kilian and BFICSI legal counsel to determine whether Mr. Hollingsworth's condition was job-related. In July, based on all available data, along with conversations with Mr. Hollingsworth's physicians, it was determined by Dr. Kilian that Mr. Hollingsworth's illness was not job-related. In view of these findings, medical plan benefits are being reinstated.

It is clear, therefore, that Mr. Hollingsworth does have a remedy. Complete development of all issues will be accomplished through the litigation he has commenced, by any difficulties he has experienced in connection with obtaining medical benefits have been occasioned by his own submission of inconsistent claims.

In the meantime we appreciate the opportunity to present this information to the Subcommittee.

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

THURSDAY, JULY 21, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 10:10 a.m., in room 2253, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Mr. **Levitas**. The subcommittee will please come to order.

This morning, we resume the second phase of our hearings on hazardous waste and EPA's management of the Superfund and related programs. We are focusing during this segment of our hearings on the subject of victims compensation. The subject matter is really one that lies at the heart of decisionmaking, both in the private sector and in the public sector, and will ultimately evolve into what is very likely a new area of the law itself in the toxic tort area. Next week we will continue this set of hearings.

As I indicated yesterday, the subcommittee intends be have hearings during the August congressional recess. The specific subject matter is not yet clear, but I would suspect there would be at least 1 or 2 days of hearings on matters involving the hazardous waste program, either on the Department of Defense aspect or the Seymour, IN site. We will make an announcement about that hopefully next week so people involved and the interested parties can make their plans accordingly.

This morning, we are particularly pleased to have a very distinguished medical-scientific panel here who will be in a position to give us their views as experts in the field; and, as well, hear from the Acting Assistant Administrator for Research and Development of the U.S. Environmental Protection Agency on the subject and also on EPA's views of the whole question of risk assessment, and what policies the agency has in that regard.

It is for that reason that we are particularly pleased to welcome Dr. Carnow, Dr. Karrh, Dr. Riordan, and Dr. Riordan's colleagues from EPA, Dr. Elizabeth Anderson and Dr. Casey Jason, and one other name not on my list.

Ms. **Lewtas**. Joellen Lewtas.

Mr. **Levitas**. Thank you.

We are pleased to have all of you here today. We will be looking forward to hearing your testimony.

At this time, I want to inquir whether my colleague, Mr. Molinari, has an opening statement to make?

Mr. **Molinari**. I do not, Mr. Chairman. I am just looking forward to the hearing today and hope that we get some answers to the questions we have been raising for some time.

Mr. **Levitas**. Thank you.

Dr. Rowland?

Mr. **Rowland**. I have no opening statement, Mr. Chairman.

Mr. **Levitas**. With that, if the witnesses would raise their right hand, please.

[Witnesses sworn.]

Mr. **Levitas**. Thank you very much. I don't want you to think you have been singled out to have the oath administered to you. This is an investigating and oversight subcommittee. All the witnesses provide their testimony under oath.

This morning, I think it would be best to hear from each of the members of the panel before the members of the subcommittee put their questions. So, why don't we just begin with you, Dr. Carnow. We look forward to your testimony. We welcome you here today.

TESTIMONY OF BERTRAM W. CARNOW, M.D., PRESIDENT, CARNOW, CONIBEAR & ASSOCIATES, LTD.; BRUCE W. KARRH, M.D., GENERAL DIRECTOR OF MEDICAL, SAFETY AND FIRE PROTECTION, E.I. DU PONT DE NEMOURS & CO.; AND COURTNEY RIORDAN, PH.D., ACTING ASSISTANT ADMINISTRATOR FOR RESEARCH AND DEVELOPMENT, ENVIRONMENTAL PROTECTION AGENCY, ACCOMPANIED BY ELIZABETH L. ANDERSON, PH.D., DIRECTOR, OFFICE OF HEALTH AND ENVIRONMENTAL ASSESSMENT; CASEY JASON, M.D., REPRODUCTIVE EFFECTS ASSESSMENT GROUP, OFFICE OF HEALTH AND ENVIRONMENTAL ASSESSMENT; AND JOELLEN LEWTAS, CHIEF, GENETIC BIOASSAY BRANCH, HEALTH EFFECTS RESEARCH LABORATORY, EPA

Dr. **Carnow**. Thank you very much, Mr. Chairman.

My name is Bertram Carnow. I am a physician, president of Carnow, Conibear & Associates, an occupational-environmental health consulting firm, and professor and director of the Great Lakes Center for Occupational Safety and Health at the University of Illinois, College of Medicine, at Chicago, and professor of occupational-environmental medicine at the School of Public Health at the university.

I am appearing at the request of the committee. I represent only myself, no organization, and the views that I present and express are likewise my own. I have been asked to discuss generally the extent of exposure as I see it, and particularly risks of acute chronic or long latency health effects, the actual incidences in my experience; and, second, the medical and scientific certainties and uncertainties associated with establishing a link between exposure and disease.

Now, diseases from toxic waste, which is the matter under consideration, are part of a group of environmental diseases. I think for the purpose of discussion, I would like to define it as I see it, because in order to establish whether such a disease is present, one would have to fulfill at least some of the definition. I feel that these are diseases that are caused by toxic chemical, physical or biological agents present in the community at levels or under circumstances which permit undue absorption into the body, this undue absorption then causing an altered cellular and organ response which adversely affects organ function. And, it is as a result of this, the health of those who are affected.

I think that toxic wastes are present in some water supplies, soils and airs in this country is not in question. I think that thousands of toxic sites have been identified. The degree of loss of containment or health impact, however, has not been quantified, and in most cases has not even been addressed. Since many stored substances are extremely toxic and many were placed in areas without regard to packaging, soil quality, or water tables, with many of these formerly unpopulated areas which are now residential communities, the problem, while unknown, may be very great.

In examining this, you have to examine how diseases surface, how the disease problems surface in relation to communities. First of all, either the community may be aware of or professionals may be aware of a large number of people, more than would normally have a disease, developing a common disease, either a respiratory disease or infectious diseases or mass diarrheas, and so on. And in these situations, a cause is sought that goes beyond individual susceptibility.

For example, in Australia, an epidemic of high blood pressure in young people was found. In pursuing this, it was found that they consumed water which contained lead. The lead affected the kidneys, which is the major target organ of lead. And so there was this epidemic of what has generally been considered a "natural disease."

I should say also at the outset that an environmental or occupational disease is a natural disease, but from an unnatural cause. That is one of the problems that we have with considering these diseases.

The second way it may emerge is that increased numbers of individuals with an uncommon disease may appear, as for example the leukemia increases in Massachusetts. Another case in point earlier, and not in this country, was the appearance of mesothelioma which is a disease caused by asbestos. Everybody is pretty well convinced of that.

Now, this is a disease that might appear in one in a million individuals in the population. In South Africa, some 40 cases were found in the community. It was found that the roads in that community were paved with tailings from the asbestos mine, and the diagnosis and association was very rapidly made.

Another way in which this may surface is increased deaths from many causes, reproductive abnormalities, premature births or increased spontaneous abortions. With regard to that, by the way, I should note—I am sure it will come up in discussion—that one way of looking at this is with the development of registries, national registries or State registries. There are very few of those in this country that address either cancer, birth defects or others of these abnormalilties They would be very useful in pinpointing problems.

Another way of looking at environmental diseases is to find toxic agents in a place and then develop a medical surveillance protocol to look for those diseases in those organ systems known to be affected by the toxic substance which may be present. And, to a large degree, this is what is happening, for example, in Times Beach and other communities that have been found to have had hazardous materials in them.

Or another way is, of course, to try to measure the amounts of the contaminant in the body once it has been established that there are contaminants in the community. Now, in many cases this is difficult or impossible, because a lot of chemicals leave the body rapidly. Many solvents do. And they do their thing as they go through. In others, you can't measure them in body fluids; for example, asbestos, because it enters the body as a dust in the lungs. The only way to measure it would be to remove lungs and look at those. Others, for example, like dioxin, are present in such small amounts in tissues that they are virtually impossible to quantitate.

Now, the problems in measuring the impact on health are many. That is one of the reasons why I think this is being addressed today. First of all, these diseases can mimic natural diseases, so-called natural diseases, because the body can only react in a certain way. The lungs can only react in certain ways—shortness of breath or cough or recurrent infection. The same is true with the liver, and so on. So that when an inflamed liver is found, it is sometimes difficult to make a determination of what has caused this inflammation.

The second problem, is that many diseases are multifactorial. That is, they can be caused by more than one cause. Many cancers, like lung cancer, can be caused by cigarettes. They can also be caused by asbestos. Each of those will increase the number of cancers in the population by 8 to 10 times. When the 2 are present together, they may increase the incidence in the population by from 50 to 90 times.

So another problem is not only that diseases are multifactorial but multiple factors may contribute to a disease. So it is not either smoking or asbestos; it is obviously both.

Another difficulty is that many of the diseases we are concerned about have long latency. That is, they may take a long time before they appear. And, because of this, they may be hard to relate to a cause.

The other problem with long latency diseases is that when they do appear, unfortunately they are frequently chronic, irreversible and, as in the case of cancer, fatal. And so every effort has to be made to find them before they appear, or at least at a point where they may be reversible, or prevented, of course.

Let me give some examples. In one community in Alabama over many years, DDT was released into the water, thousands of tons. The people in the community drank the water, bathed in the water and ate the fish from the water. A large number of individuals were affected and many of them developed diseases which were not recognized as being environmental diseases but were seen by different physicians and called many different things.

Another, for example, related to lead. We found in a number of instances downwind from lead smelters of lead poisoning in communities. Now, the children in those communities were lethargic. Some of them had anemias. Some of them were mentally retarded. Some of them had other symptoms, none of which were related to lead until they were looked for, and it was determined that these children had high concentrations of lead, those that were living downwind from this smelter.

So the problem of risk and the problem of how many people have been affected, I believe, has barely been raised. I think it may be akin to the problem that we had with black lung where we thought there might have been a few thousand cases in the community. When compensation was offered to black lung victims we find ourselves now with more than 300,000 miners or their families being compensated. So that it may well be that some of the things that we are seeing may be the tip of an iceberg.

Certainly, most of us feel that cancer is an environmentally related disease. One has only to look at the National Cancer Institute maps to understand this, because there are hot spots of cancer in this country, unquestionably. If we can find those factors which go into the development of cancer, or causation of cancer, then we can eliminate this group of diseases which kills 1 out of 4 Americans, 650,000 new cases each year, 350,000 or more deaths.

Let me then address the second question, that of medical scientific certainties and uncertainties. Dr. Shirley Conibear, my colleague, and I have developed models or ways of looking at the problem. If you can do an epidemiologic study, you can come up frequently with statistically related associations which may be very useful.

The problem we now have in the work place as well as the community is that there may be just a few cases, or there may be subclinical cases. And so what we need to do is to establish methods for estimating the probability that a disease is related to an external or environmental cause, because all we are dealing here with are levels of probability.

When we talk about causation, what we talk about is how probable is it that a disease is caused by an exposure. To do this, we have to consider a wide range of parameters. The first is to make a toxicological assessment of the materials, the substances, that are found. This tells us first about how toxic an agent might be and how much of a problem it might be; and, second, it tells us also about the possibility that it might be absorbed into the body. I will address that in a moment.

Second is to make an environmental assessment because that helps us determine the probability that a material is available—if you consider the definition—that a material is available for absorption and that it is present in a place and in a way that it may be absorbed by individuals.

The third major component is to look at the community at large and try to identify those individuals in the community who may be at high risk either because they are children, pregnant women, aged individuals with chronic disease, cigarette smokers, and so on and so on, because those are the individuals who might be expected to show the first evidences of disease from an external cause, because they are at higher risk.

Finally, to carry out medical procedures will help to determine a relationship. And the way to do that is, after we determine what materials or agents are in the environment, we set up a set of tests which will look at those organ systems which may be affected by those substances in the environment. If they are, then that enhances the level of probability.

Now I would like to take just a few moments to run through briefly some of these parameters and use as an example one which I believe you have already been discussing and one which has become a public household word. That is, the problem of dioxin. In making a toxicological assessment, the first thing you might look at is intrinsic toxicity of the agent. Dioxin, as we know, is probably the most toxic of all man-made chemicals. It is capable of killing a fetal animal at five parts per trillion, an extraordinarily low concentration.

Second, we would look at how can this chemical get into the body. In the case of dioxin, it can get in through the skin, through the respiratory tract, it can get in through the mouth. So there are multiple portals of entry. What the body sees, of course, is the total body burden. That is the one that is of concern to the body.

The third is the form of the agent. Is it in the form of something which can be breathed, that can be drunk, and so on? We then look at the whole question of how long it stays in the body. We call that half-life; how long does it take before it is broken down. Well, something like dioxin, because it has a chlorine at the 2378 position, is very difficult to destroy, because those are positions that this chemical is destroyed at and these positions are blocked by chlorines and therefore it can't be destroyed easily. So it stays in the body for a long time. It is not easily degradable.

We then look at the question of where is it stored. We find dioxin is stored in multiple organs, including pancreas, adrenals, kidney, the brain, and so on. We then ask the question: What are the known target organs? From a huge collection of data which has been assembled since 1953, we know that dioxin can affect virtually every major organ system in the body.

Finally, we look at what are the rates of excretion or how is it excreted. We find that with this chemical, it is excreted very slowly, if at all, in humans once it fixes in tissue. So that would be a toxicologic assessment.

Based on the answers to this question, one might present, on a scale of 0 to 10, the probability that toxicologically this may be of significance to the community in terms of health. The second thing that would be considered are the environmental and industrial hygiene assessments. For example, emission and production data of plants in the area; changes in processes and materials and controls; when these occurred in industries whose wastes were dumped or which were in the area.

We would look at the degree of containment of substances which are already in the ground by looking at air, dust, water, soil samples, to see whether or not it has gotten out of where it was originally. We would look at the probability of containment by looking at the depth of burial of waste, at the porosity of the soil, the level of the water table in relation to the dump, the packaging of the waste and at the length of time it has been there. All those are important questions in making a determination of whether or not it is available to the community.

With dioxin, we know that this was in one place. It was removed; it was spread over large areas. And it still is present in many of these areas.

Then we look at the probability of physical contact. For example, did people who are exposed—were they wearing protective clothing, and so on. In the case of communities, generally this is not the case. You have individuals moving around, children playing in the streets, food and gardens, all things we do in our communities.

We then try to look at the community itself. Is this a community that has many children? Is it a community that has many women who may become pregnant or who are, or who have been? Is it a community which contains large numbers of older people who may have chronic disease? All these are important in making a determination of what portions of that community we might want to survey in order to make a determination of what the impact might be of a toxic material which has been discovered in that community.

Finally, as I pointed out, we would do measures of either the effects on organ systems, which might be affected by this material, or measurements of body burden; that is, to look at the body and body fluids to make a determination of what the lead levels might be of mercury or cadmium or whatever, if that is possible. In some cases, it is. Then, after all of this is found, we would then ask a number of questions. There are many questions.

But, among those, we would ask the question: Is the relationship between the disease and exposure reasonable and logical? Was the dose sufficient to cause disease in the individuals who are diseased? Is the organ affected and pathology we find what might be expected from such an agent? That becomes very important. And, are multiple organs which are known to be affected by this agent affected, because there are many factors which can cause a disease of the liver? But if you have a disease of the liver and a disease of the brain and a disease of the peripheral nervous system and disease of other systems that we know, for example, that can be affected by dioxin, then it becomes one of these questions of, if it walks like a duck and talks like a duck, it in fact is. This is the way we get to a diagnosis of relationship of disease to a cause.

Then we ask the question: Are those who are expected to be at highest risk due to dose or other factors, the ones who develop the disease? Finally, we ask the question: Are others—not all others, because there are differences in susceptibility—but are others who are similarly exposed, similarly affected? If you can answer those questions in a reasonable way positively, then one has a responsibility to make an assumption that there could be a strong association which is akin to causation in disease between an exposure and a toxic agent.

I think this is, in brief, my statement. I have prepared what is a larger document which you may look at. One of the things that this document points out—and I would like to call the committee's attention to it are the few trained individuals, including physicians, in this country, in this field of environmental and occupational medicine. And while this is not a major problem in toxic waste, it is one of the problems that we have in finding individuals who may have been affected, because physicians generally are not trained to look for cause, but are trained to diagnose and treat disease. This is another area which I think this committee may not be addressing, but one which needs to be addressed.

Thank you very much.

MEDICAL AND TOXICOLOGICAL CONSIDERATION IN DETERMINING PROBABILITY OF CAUSATION OF ENVIRONMENTAL DISEASES

Bertram W. Carnow, M.D. and Shirley A. Conibear, M.D., M.P.H.

Clinical environmental and occupational medicine is at the interface of diagnostic and therapeutic medicine on the one hand and preventive medicine, including epidemiology, toxicology, and biostatistics on the other. It extends diagnosis of disease to include identification of cause. It applies the data base of epidemiology and toxicology to a single or relatively small number of cases in order to accomplish this end. In the absence of large cohorts or groups of cases, standard methods for establishing significant relationships and extrapolating probable causation do not apply. New ways of assessing the level of probability that an environmental or occupational agent and a disease are related must be utilized.

As the basis for discussion, the definition of environmental or occupational disease is one caused or significantly contributed to by one or more toxic chemical or physical agents found in the environment or in the workplace, present at a level and under circumstances which permit undue absorption and retention in the body and which result in bringing these agents into contact with cells or organs sensitive to their toxic effects. These agents then cause an altered cellular and/or organ response which adversely affects organ function and as a result, the health of the person involved.

I. Clinical Medicine: State of the Art

An assessment of the state of the art requires a description of both the clinical medicine model as it has been taught and practiced over the years and the occupational (and environmental) medicine model. Most of the clinician's training, knowledge and skills, relate to the diagnosis and treatment of disease. Until recently little or no consideration was given to seeking a cause except in infectious diseases where the organism had to be identified in order to treat the patient. More recently genetic and dietary factors and cigarettes and drugs have been causally associated with diseases of the heart, lungs, liver and other organs.

In seeking a diagnosis, the physician attempts to determine if a disease is present, the organ or organs involved, and the nature and extent of involvement. The method used follows a specific pattern which all physicians learn during medical school and residency training. This consists of data gathering, drawing a diagnostic conclusion based on choosing the most likely disease, intervening with treatment, and observing the patient to determine whether treatment is successful. Data gathering consists of questioning the patient regarding past medical history, time when first symptoms were recognized, patterns and severity of symptoms, and other information such as family history and lifestyle. For some diseases, i.e. chronic pulmonary, hepatic, and lung cancer, physicians frequently take a history of family disease (genetic), diet, cigarette smoking, alcohol, drugs or trauma with a view towards establishing these as significant factors in the causation of the disease. Physical examination is then performed and based on it and the history, laboratory tests are ordered. These generally consist of tests to determine levels of organ function or dysfunction except in the case of infectious diseases where blood, urine, feces, or sputum analyses may be performed in a search for causitive biological agents. Tests are generally carried out with specific organs in mind and are to a large degree oriented toward defining levels of organ function. The diagnosis of disease is based on matching these findings with a known clinical syndrome, taking into account the pattern of disease prevalence in a geographic area within a particular socioeconomic or ethnic population known to the physician through clinical experience. Treatment is then prescribed and patients followed to determine whether treatment intervention has been successful. Reassessment of diagnosis generally occurs when the treatment does not appear to have resulted in a return to a healthy state. Since the key to diagnosing a disease as environmental or occupational is the establishment of cause, where this is not done through relevant history or laboratory tests, and particularly under circumstances where physicians are not trained in toxicology, epidemiology, or biostatistics, the diagnosis is only rarely made.

This is not true for all medical disciplines. The majority of occupational diseases are dermatologic in origin, so that dermatologists have long been aware of the cause or relationship between many skin irritants and sensitizers and dermatologic diseases. Allergists, very early, came to recognize that the environment along with genetic and other factors played an important role in disease causation. The development of scratch tests, intradermal tests, and RAST were all part of the search for etiologic agents. Physicians specializing in pulmonary disease and radiology also have known about pulmonary disease from the fibrogenic dusts and have related abnormal x-rays to occupational exposures. Psychiatrists also probe for environmental causes of behavioral abnormalities, but generally these do not include the physical or chemical environment.

II. Occupational and Environmental Medicine: State of the Art

The clinical methods used to diagnose occupational and environmental diseases include the identical components described in the state of the art in clinical medicine. In addition, however, the sciences of epidemiology, toxicology and biostatistics, and the occupational and environmental data base are utilized in arriving at a clinical diagnosis and, in addition, in finding the cause.

The problems involved in establishing environmental and/or occupational factors as causative are many and provide serious challenges to the physician. These will be discussed in detail, but two types of problems should be noted. Many agents can cause similar, if not identical, diseases of a particular target organ and when present together may greatly increase the possibility that disease will result. For example, the lungs of a welder who smokes and lives in an urban environment are assaulted by metallic and other fumes at work, and cigarette smoke and air pollution at home. The result is often chronic obstructive lung disease. Additionally, some toxic agents are available from multiple sources with each source playing a role in causing disease. Carbon monoxide is one of those and is present not only in many industrial settings but also in cigarettes and automobile exhaust. Where exposure is to relatively low levels of the toxic agent over a long period of time, the symptoms and abnormal findings may present very subtlely. In such cases there is also the problem of long latency between onset of exposure and disease. Since many toxic agents affect the lungs, liver or nervous system, synergistic effects of cigarettes, alcohol and drugs increase the difficulty of establishing major environmental causative factors. The problem is also made more difficult when the cohort under study is relatively small since many of these diseases, for example cancer, usually require large members and a long period of observation to separate "background" incidence from an excess due to exposure. The differences in risk of various populations because of cultural or socioeconomic factors may also be significant and are compounded by the variability of risk in groups of individuals within a population based on many factors, which will be discussed. The occupational and environmental medicine clinician faces all of the above problems when attempting to diagnosis a disease and its' cause. There is the added problem for the clinician of carrying out this activity on a single or a few cases where no statistical assessment is possible in the classical sense.

III. Clinical Diagnosis of Environmental and Occupational Disease and Its' Cause

The diagnosis of cause is based on establishing a high level of probability that a disease syndrome is related to an exposure. This can only be done by considering a multiplicity of factors which include the availability of the hazardous agent, the probability that it has entered the body, evidence that it is present in undue amounts and whether the individual is at enhanced risk for other reasons. In carrying out this estimate of the level of probability, factors which must be considered in the history include a toxicologic and environmental exposure assessment and the individual as a biological risk. Other data obtained include laboratory tests which measure levels of undue absorption of toxic agents, tests to determine the presence of abnormalities of function of organs or organ systems, and the physical examination.

A. Toxicologic documentation

Toxicology data gathering will be considered in detail in other presentations. Discussion here is confined to examining those components obtained as part of the medical history which help to determine if undue absorption has taken place, what the excess body burden might be and its' potential for causing disease.

The ability of an agent to enter the body through one or more portals should be determined in order to assess whether undue absorption might have occurred. Some chemicals in liquid or solid form enter only through the GI tract. Others, for example dioxin, methanol and many solvents, can enter through the skin and the lungs as well as by ingestion. The percent absorbed into the body after entry is also of considerable importance. For example, lead is absorbed to the extent of five to ten percent of the total ingested in most individuals, although in young children it may be much higher. On the other hand 30 to 50% of inhaled lead may be absorbed into the body and therefore represents a much greater threat to health.

The physical characteristics of the agent are also important factors in estimating body burden, particularly when considering aerosols and particulate. In most cases it is necessary for particles to be five microns or less in size in order for them to penetrate beyond the mucociliary defense mechanism into the lower portions of the lungs where retention time and therefore absorption may be markedly enhanced. This is not necessarily true, particularly of asbestos which, because of its' great length to width ratio, acts as a small particle. Aerosolization of substances may also enhance the penetration and dissemination of a toxic agent through the lungs. The temperature, vapor pressure and the molecular weight are additional factors acting to increase or decrease absorption into the body.

The ability of the organism to degrade, detoxify and excrete a substance determines to some degree the substance's availability to various tissues and organs, and its' ability to accumulate and to cause toxic reactions in the body. Accumulation and storage of toxic agents depends to some degree on the rate of excretion. Where the major routes of excretion are known, for example, through the kidneys, quantitation of body burden may be carried out by examining the urine for the agent or its' metabolic products. This has limitations since with many substances there appears to be poor correlation of urine levels with health effects and even with true body burden.

Tissue or organ storage is another factor in determining the probability that a significant health effect will occur. In the case of a substance like lead, 90% of it is stored in the bone, where it has little effect. The important site of action in this case is not the organ of storage, but other organs including the nervous system, kidneys and blood forming organs which are the major target organs for lead. This may also be true with other chemicals. This knowledge is critical since the measurement of effect will focus on target organs.

B. Environmental and Other Exposure Factors

It is essential to consider environmental exposure factors, specifically levels of toxic agents in air, water and soil, in estimating the probability that undue absorption has taken place and that a toxic agent is present in the body at a level sufficient to produce disease. Measurements of all three may be necessary not only to determine the levels of toxic agents but the areas contaminated and in some cases the source, which may be an industrial plant or stored toxic wastes. Where an industrial plant or other point source is suspect samples must be taken up and down wind from such facilities using prevailing wind speed and direction to predict areas of high and low concentration. We found soil and dust samples to be particularly useful in determining long term deposition and therefore chronic exposure of populations in an area. Soil samples taken at 16 compass points, at variable distances from a lead smelter and at variable depths, were highly correlated with the effects on the population around the plant.

Emission and production data may be extremely useful in predicting problems. In El Paso, Texas we predicted that children with lead poisoning would be found as a result of exposure to lead emitted in high concentrations from a smelter. This prediction was based on examining emission data which were reviewed for a completely different reason. Testing revealed large numbers of children living down wind to have undue body burdens of lead with many showing evidence of lead intoxication.

Changes in production process, materials used and emission controls are additional necessary pieces of information. Another group, a community of Mohawk Indians, were exposed to an estimated 25 million pounds of fluoride dumped on their island from an aluminum smelter. Information about changes in process with subsequent reduction in emissions made it possible to provide a reasonably good estimate of the levels of fluoride available to the population. As a consequence a study is being carried out to examine the health impact of fluoride on this exposed community.

Additional environmental factors which require consideration include the general characteristics of an area such as temperature, humidity and rainfall. El Paso's warm and dry climate enhanced the amount of lead dust present on surfaces and in the air, resulting in increased exposure of children to the lead. Most of the houses had dirt floors and the roads and playgrounds were unpaved, which also increased exposure. Other environmental observations which may be useful in predicting that a problem exists includes looking for damage to fish, plants or animals in the region, rapid deterioration of metals, fabric, and paints, etching of glass, or the presence of odors. On the island exposed to fluoride, much of the vegetation had died along with virtually all of the cattle, suggesting a high level of exposure of all life on the island.

C. Biological Host Factors

In every population there is considerable variability of risk among its members even at the same dose of an agent. While many factors affecting risk differences are unknown, some are well established and need to be assessed. An important consideration in assessing the probability of a causal relationship is whether or not those expected to be at highest risk as a result of factors other than intensity of exposure, are also the ones who appear to be the first and most seriously affected.

Genetic factors in risk determination have received little consideration but may be of importance. For example, individuals with enzyme deficiencies of G6PD or sickle cell trait are more susceptible to the effects of some toxic agents on the red blood cell. Others with alpha-1-anti-trypsin deficiency, asthma or allergies might be more sensitive to toxic inhalants. Another example, the finding that those with increased aryl hydroxy hydroxylase (AHH) induceability, a genetically determined trait, are at greater risk to PAH induced lung cancer is of considerable importance. It is important that much greater research efforts should be made to find other factors which increase or decrease individual susceptibility to disease. Elaboration of additional genetic risk factors will enhance our ability to quantitate the variability of risk in population groups as has been done with cigarette smoking, cholesterol and hypertension in cardiovascular diseases.

Age must be considered since the very young and the aged, particularly those with chronic diseases, appear to be at considerably higher risk. Studies showing the causal connection between various dyes and bladder cancer also revealed that those initially exposed before the age of 25 as compared to those who began their exposure after this age, even where the duration of exposure was the same, may have been at increased risk for the development of cancer. Very young children appear to have increased sensitivity to many agents, particularly metals and solvents. In the case of lead for example they exhibit much more serious acute and chronic disease effects at lower blood lead levels than adults. The reasons for this include greater absorption from the GI tract (up to 40% of ingested lead), a poorly developed blood-brain barrier, and nutritional factors (decreased calcium or iron). The fetus is probably the most sensitive of all particularly when the toxic agent can cross the placenta - for example, lead, mercury, and lithium. Sex differences may be important where individuals are exposed to hormones, drugs, or chemical wastes or fumes which may affect reproductive organs. Additionally the physiologic stress imposed by pregnancy may be a factor in altering risk.

Those suffering from chronic diseases also represent a cohort generally at higher than normal risk when exposed to a wide variety of toxic agents depending on the organs affected and whether they are also target organs for the toxic agents. This is not only true in relation to causing further damage to organs with already reduced functional capacity but in the case of organs serving as excretory routes, such as the kidney, may result in increased body burden as a result of increased retention of a toxic agent. Chronic liver disease may lead to decreased detoxification of toxic substances, again increasing retention in the body.

Habits and cultural differences may alter the probability that an individual exposed to a toxin will develop a disease or that the disease developed is primarily related to a toxic exposure. These include cigarette smoking (possibly the most confounding variable of all), alcohol intake, nutrition, and socioeconomic status. Each may enhance the potential for developing disease due to exposure to environmental toxic agents. Where the exposure is small and the "habit factor" is great, there may be difficulty in estimating the role of the environmental factor in disease causation.

There are many other factors but only two will be mentioned. The first is a positive past medical history before exposure. The history of disease present before exposure doesn't necessarily reflect reduced impact by the toxic agent. It only suggests that health problems were present before exposure and that the person may in fact be at high risk because of lowered adaptive capacity. It does not mean that the environmental agent has not caused disease, because in fact those with previously diseased target organs generally are at enhanced risk. The second is drug intake, since these may be synergistic, or antagonistic with toxic agents or may themselves be major causative factors in disease.

D. Effects on Biological Systems

Examinations for the effects on biological systems usually follows the determination that an individual or community has been exposed to higher than normal levels of a toxic agent and that the toxic agent may have been absorbed into the body. It also usually follows measurements of undue absorption, although with some materials this is extremely difficult if not impossible, for example, asbestos. The presence of toxicants in the body in undue amounts suggests that there has been undue exposure but gives no information regarding negative health effects, only the probability that such effects may have occurred. The absence of findings of undue absorption, particularly of a toxic agent which is stored where it cannot be measured, rapidly metabolized, or excreted from the body does not even provide that kind of information, so that frequently environmental data have to be relied on to conclude that enough had entered and passed through the body to predict that undue effects on health may have occurred.

A determination of whether or not negative health effects have resulted requires taking the history of exposure or residence in an area in which toxic wastes were present, a past history of health status, and the development of symptoms. From these, and with some knowledge regarding which toxic agents were present in the individual's environment and the major target organs generally affected by this agent, relevant diagnostic procedures can be carried out. This is then followed by a physical examination and from all of these a determination made that a disease is present or not, which organ systems have been affected, and the nature and extent of the effect. These constitute a disease syndrome and, particularly where multiple organs appear to be involved, an attempt is made to relate all of them to a common or single etiologic factor. In some cases, there are unique factors or findings present which permit the determination that a "classic" environmental or occupational disease syndrome exists.

E. History

The classic clinical history obtains information about the time of onset, the progression of disease, and the duration and/or periodicity of symptoms by asking these and other questions used in standard medical practice. In addition, however, a history is taken to determine if others in the community have been affected, the relationship between the onset of symptoms and date starting residence in the community as well as information regarding environmental exposure and toxicology previously discussed. A history of past health and one which may elicit genetic abnormalities is important in assessing the risk of the individual as a biological entity.

Symptoms are critical in making a diagnosis and eliciting them is an area where most physicians possess considerable skill. Where it is suspected that a particular substance may be involved, questions can be directed toward determining whether symptoms known to be caused by such a substance were or are present. This is often the area which is not considered in general medicine. Many cases of lead colic are diagnosed as cholecystitis, ulcer or appendicitis and in some cases individuals are subjected to multiple surgical procedures before a diagnosis is made. Where symptoms suddenly surface, are not continuous or have a temporal pattern, possible changes in environmental exposures should be sought. In one situation, children who were unknowingly suffering from chronic lead poisoning suddenly developed acute symptoms. This was eventually related to the discontinued use of a baghouse with a marked increase in airborne lead in the air of the community. Under some circumstances individuals leaving a community who may have "accommodated" to an environmental stresser, that is, do not have acute disease because exposure occurs over a long time period, suddenly become ill on returning to the area. In these cases a syndrome similar to fume fever may occur. This is a disease which occurs on Monday when workers who have been away for two or more days are exposed to zinc, brass or other metal fumes. Where numbers of people are found to have onset and progression of symptoms at about the same time and where the symptoms are similar, a common etiologic factor should be suspected. This is certainly the case in infectious disease epidemics and may also be the case where environmental agents are the cause.

F. Diagnostic Test

In considering the types of diagnostic tests to be performed many factors must be considered. These include:

(a) Numbers of individuals to be tested.

This is the first and often, the most critical consideration when carrying out diagnostic testing particularly in a community where a common environmental etiologic agent is being sought. If it is felt, based on all of the considerations previously discussed, that a large number of individuals may have been exposed, or, if there appears to be a high incidence of clinical disease in the community, it may be necessary to test many hundreds of people. Where this is the case sharply reduced questionnaire length in taking histories, sophistication of tests and time that the tests take to perform, become critical considerations. Where only small numbers of individuals are being tested this does not obtain. The decision of whether to test only those who appear to have been most heavily exposed to determine whether there has been negative health impact on them as "test cases" for the community is frequently a difficult one. There may be some danger in having the rest of the community wait until initial testing on the smaller group is carried out.

(b) The location of the community.

The location of a toxic dump, contamination of a water supply or other environmental problem is frequently in a community which is physically isolated. Limitations of personnel, transportation of equipment and required storage of specimens are among many factors which must be considered in deciding which tests will be carried out.

(c) The cost of the test.

This may often be the limiting factor in studying a community particularly when the numbers to be tested are large. For example in screening for lead a zinc protoporphyrin test (ZPP) which requires only a drop of blood, costs only a few cents to do and is easily reproducible on site may be much more desirable than a blood lead which costs considerably more, or a test for ALAD which in addition to the cost must be carried out promptly. There are many other examples of ways in which cost can be reduced without sacrificing to any signficant degree the usefulness of a test. The use of a PA chest x-ray instead of including a lateral view reduces cost considerably in a first round of testing as is the use of a hematocrit or hemoglobin instead of a CBC in screening for anemia.

(d) Acceptability by the community.

There are many test that groups and communities will not accept easily, particularly those of an invasive nature, such as tissue biopsy or bone marrow aspiration. Tests which may be painful such as peripheral nerve velocity conduction, EMG, or proctoscopy will also encounter considerable resistance. Others which may cause embarrassment or carry a stigma, for example production of a sperm specimen or "psychological tests" also often encounter difficulty. In one study, people informed that a neurobehavioral battery of tests was similar to the testing of their reflexes accepted testing while mention that psychological tests would be performed resulted in mass refusal.

(e) Time needed to complete the test.

A neurobehavioral battery may require two or more hours of time to perform, trained personnel to administer the tests, and skilled professionals to score and interpret them. Where large groups are being tested this becomes almost prohibitive because of cost, personnel and time.

(f) Morbidity and mortality.

Most testing procedures carry with them a very small risk. Some, including invasive procedures or those where dye injections are required, carry an increased morbidity and in some cases even a small mortality risk. Invasive procedures, tests such as EDTA challenge and others should only be carried out after serious consideration of their need, and only by skilled and experienced professionals and where some follow-up observation is possible.

(g) Test sensitivity and specificity.

The determination of whether or not to carry out tests which may result in many false positives as compared to many false negatives is generally determined by the importance of not missing any cases in the community. During the initial screening of large communities of individuals, those tests which are more "sensitive" that is which include all positive cases in addition to some false positives are generally more desirable. During a second round of examinations after the entire community has been screened, tests specific for a disease in which only few false positives result may be more useful.

(h) Personnel and equipment.

Depending on the location of the community to be examined these may be important considerations. Equipment carried into the field must be durable, stable and portable. In urban communities where facilities and equipment are easily available and repair of equipment obtainable this is not a serious consideration. In many cases, however, toxic waste victims are in out-lying or rural areas and this becomes important. The required number of personnel and their levels of training and expertise frequently determine the cost of testing as well as the numbers of individuals that can be examined. Local individuals in communities being studied often can be trained to assist in carrying out many necessary procedures if large numbers of people are being examined.

(i) Test preparation.

Those test which require special procedures such as restricted diets or a 24 hour urine collection are often very difficult to obtain. In examining groups of workers exposed to arsenic it was necessary for them to stop eating fish or seafood which might contain this chemical for three days before the test in order that the urine might be appropriately examined. Since, in this community, fish and other seafoods are an important part of the diet this was very difficult to achieve. Fasting blood is frequently difficult to obtain in working populations particularly if they are on shift rotation, as are meat free and other types of special diets.

A wide variety of diagnostic tests are used in clinical medicine. To a large degree they examine the level of function of organ systems and when these are inappropriate or abnormal a conclusion is reached that disease of this organ may be present. Where multiple organ systems are found to be abnormal, an attempt is generally made to integrate these findings into a single disease diagnosis. Environmental and occupational medicine utilizes in addition a wide variety of tests to determine whether toxic agents are present in the body and the levels at which they are present.

The first group of tests include those which measure total body or organ concentrations. These are the most specific tests since they look for the presence of the toxic agent in order to determine its' presence and concentration in the body. They are carried out by examining the appropriate body fluids including the urine, blood, spinal fluid, saliva, sputum, hair, nails, feces, sweat or exhaled air. While these are specific in determining whether the agent is present in the body they may not provide accurate information about dose or any information about the toxic effects on body organs or tissues. Lead for example may be measured in the blood, urine, feces, hair and nails, but in fact 90% of all the lead in the body is contained in the bone where without carrying out a bone biopsy it cannot be directly measured, although x-ray findings of density in the long bones provides qualitative evidence of a heavy bone burden. While there is some evidence that blood lead provides important information regarding whether levels currently present are toxic or not, it too only indirectly provides information regarding how much is in the body and it also, fluctuates depending on when exposure took place so that levels which may have been high in the past may be normal when obtained. For this reason other body tissues have been used to assess chronic exposures such as teeth in children, which is a measure of lead during tooth development or zinc protoporphyrin which reflects the replacement of iron by zinc in the red blood cell and therefore a measure of body burden over a period of months. Hair lead provides some information regarding past body burden but has not been shown to correlate highly with toxic effects. One additional method for assessing levels in the body is a provocative chelating test where urinary lead is measured before and after a dose of EDTA. A sharp increase generally means that other tissues, particularly the bone, may contain large amounts of this metal.

A considerable amount of work has been done on the usefulness of measurements of toxic agents in various tissues in estimating body burden. Studies carried out on Minamata Bay victims, individuals who ingested large amounts of mercury from contaminated fish, found that blood and hair provided reasonable estimates of body burden. In a study of workers in multiple plants who were exposed to lead, we found that ZPP correlated reasonably well with exposure and at an FEP level of 50 micrograms per dl of blood no workers were found with blood lead levels above 40 micrograms per dl of blood. In another study, workers exposed to arsenic and with arsenic intoxication were followed with multiple examinations over a three year period. We found a highly significant correlation between exposure and hair levels of arsenic. We found no correlation with urine. Urinary arsenic appears to be a useful measure only in determining whether this chemical had been absorbed into the body over the past 72 hours. The hair on the other hand was a much more accurate reflection of the amounts absorbed by the workers in our study. While previous studies claimed that external arsenic contaminated hair specimens and made it impossible to use hair as a tissue for measurement, we did not find this to be the case. This entire area is one where a considerable amount of research effort should be expended. Studies, particularly those in which levels of toxic agents in various tissues and fluids are compared with exposure of individuals and symptoms and disease, should be carried out.

A second group of laboratory tests provides us with an indirect measure of body burden by examining urine and in some cases feces for metabolic degradation or by-products. Toluene, for example, exits through the urine as hippuric acid which can be measured. There are many other similar examples. Others which in fact are measures of interference with biochemical function also provide indirect estimates of body burden. For example, lead at almost any concentration interferes with ALAD which is essential in the production of heme and processes delta aminolevulinic acid in the body. The reduction in the enzyme ALAD interferes with this process leading to an increase in delta-ALA in the blood and urine where its levels can be measured. Levels of ALAD can also be measured although with some difficulty and have been shown to have an inverse linear relationship to lead at a level as low as 10 micrograms g/dl in the body. Another example is acetylcholinesterase which is decreased in the body in the presence of organophosphate pesticides. These latter tests, measure body burden and also the level of interference with physiologic function and therefore increased physiologic stress if not disease.

The next group of tests, those which measure the health or disease of the major organs and organ systems, are familiar to all medical practitioners and are used with great frequency in the practice of clinical medicine. These measure organ function in a variety of ways in order to determine whether they are malfunctioning and therefore are diseased.

The first group are those which measure impaired or diminished function, such as muscle strength, nerve conduction or spirometry. In these tests, muscle strength is examined to see whether it is diminished, nerve conduction to determine whether there is slowing of the impulse and spirometry to look for the inability of the lung to contain a normal volume of air or to force it out of the lungs as rapidly as it should. Another example of reduced function includes audiometry, that is, hearing ability at certain frequencies.

Another group of tests examines organ systems for increases in function. These include hyperirritability of muscle or hyperactive reflexes on the physical examination. A third group measures deviation from normal patterns. These include EEG, and ECG as well as x-rays.

One other group that should be noted are tissue tests. These include lymph node, liver, lung, muscle or other biopsies or bone marrow examinations. They may be examined for levels of toxic agents, for example, by ashing tissue, or for histopathologic changes which, while frequently nonspecific, may aid significantly in diagnosis. An example of this is beryllium which causes a granulomatous lesion similar to that of sarcoidosis, where ashing of the tissue and testing for the metal can pinpoint the diagnosis.

The problem with tests of organ function is that they are generally nonspecific since organ systems can respond only in a limited number of ways to toxic and other disease producing agents and differentiation of cause is often impossible from tests alone. It is however an important component of the "clinical syndrome" when considered together with the history and all of the other data which have previously been discussed.

G. Physical Examination

The physical examination in our experience has proven to be the least sensitive group of tests in providing information about toxic exposures. This may be because surfacing of abnormalities in such examinations generally occurs only in severe acute, or far advanced chronic, disease. Physical examination of the skin, however, may be extremely useful in some conditions. An example is chloracne, particularly in children after exposure to dioxin, PCBs and other similar chlorinated compounds. Another is keratotic skin lesions and skin burns from arsenic exposure which can be useful in making a diagnosis. Examination of the skin can also be very important where exposure to carcinogens may be suspected or has occurred. More than a million skin cancers occur each year, more than all others combined and because they are visible they are frequently detected early. They therefore represent an extremely important signal lesion of effect as well as exposure since most carcinogens are carcinogenic for more than a single organ. Neurologic examination may also sometimes reveal abnormalities where there are few or no symptoms including abnormal reflexes or movements, or muscle atrophy. In general the physical examination at best serves to confirm the history, symptoms, laboratory and other test findings.

IV. Clinical Syndrome

The large number of variables operating in the development, intensity and extent of disease syndromes makes it extremely difficult to describe a "classic" syndrome resulting from absorption of a toxic agent into the body. For example, the form of the agent can often determine the level of absorption and action in the body. Organic forms of metals such as lead or mercury may cause a disease picture very different from that occurring from an inorganic form. Also in the latter group the more soluble the form the greater the absorption so that intensity and extent of disease may vary greatly. Further, absorption of a large dose over a very short period of time may result in a remarkably different "syndrome" than lower level exposure over a very long period although the total dose may be equivalent. The body generally reacts to toxic agents as it does to any other physiologic insult. For example, an acute blood loss from 16 to 8 grams in a period of minutes or hours frequently leads to shock, renal shut-down and often death. On the other hand individuals who develop anemias over a long period can be seen ambulating with 5 or 6 grams of hemoglobin. Children living close to and downwind from a lead-zinc smelter were found with levels of blood lead exceeding 170 micrograms per dl of blood. While some of them were anemic and most revealed evidence of brain damage, they appeared to be functioning physically. Many were lethargic, had low grade gastro-intestinal complaints, were irritable, and had headaches, but much of this was ignored because these symptoms were not dramatic. In Chicago on the other hand, a child eating flaking, heavily leaded paint and developing a level of 170 micrograms almost certainly would present with encephalopathy, cerebral edema and coma.

In addition to the differences between chemical forms and acute and chronic exposures, the populations at variable risk will exhibit very different syndromes from each other. The child with acute lead poisoning will exhibit a very different set of symptoms from an adult. The chronically exposed children that we saw, on the other hand, exhibited relatively similar symptoms to the adults except that the amount of brain damage found was considerably greater. The reason for this may be that in young children more than 5%, in fact up to 30 or 40%, of the lead ingested may be absorbed into the body. Also, in very young children the blood-brain barrier is not well formed, permiting more lead to enter the brain. Additionally, the increased metabolic activity of growing children is also a factor. In both groups, however, adults and children, the ultimate target organ does appear to be the kidney.

Some "classical" clinical syndromes have been described and are almost pathognomonic in that they have very unique features. Asbestos is certainly a classic case in point. Montague Murray in 1900 was able to relate the pulmonary disease he found on examination and at autopsy of a worker to asbestos exposure. The worker he saw pointed out that others working in the same area of the plant died from lung disease and had the same symptoms he had. Massive calcification of the pleura which Murray had never seen before led him to his conclusion that asbestos inhalation caused the disease. The clinical syndrome of a history of exposure to asbestos, asbestos bodies in sputum or tissue, progressive shortness of breath, a restrictive and ultimately obstructive defect of pulmonary function, a diffusion defect, bilateral lower lobe fibrosis on x-ray with, in some cases, honeycombing of the lung, pleural plaques on the diaphragm, thickening, fibrosis, and calcification of the pleura, clubbing of the fingers and rales at the bases are all components of the syndrome, although rarely are all present in one case.

Mesothelioma and cancer of the lung and other organs may also be considered part of this syndrome, that is diseases caused by asbestos. With some other agents there are also so-called classical syndromes. Fume fever's characteristics have been noted. Other fibrogenic dusts besides asbestos such as beryllium, silica and coal produce fairly characteristic syndromes when fully developed. Even in these cases however, other diseases many be mimicked. For example berylliosis looks very much like sarcoidosis and is a systemic disease involving the same large group of organs. History of exposure, ashing of tissue and examination of it for beryllium confirms the diagnosis. Lead encephalopathy in children would be considered "classical" except that encephalitis from other causes may present a somewhat similar picture. The history of pica in a child living in an old tenement with flaking paint, exposure near a lead smelter, finding of lead in the gastro-intestinal tract, evidence of increased blood lead, anemia and other similar findings would help to differentiate this syndrome. Some toxic agents tend to have a predilection for certain systems. Metals generally affect the cytochrome oxidase system, inactivate sulfhydryl groups and interfere with cell metabolism. The effects are related to this. Many of them are also excreted through the kidney so that this organ in addition to the central and pheripheral nervous systems is generally affected. Here too, however, there may be endless variations.

Solvents are another large group which have some general characteristics although there are wide variations in clinical syndromes. They tend to enter the body through multiple routes including the skin. Because of their chemical nature they also tend to defat the skin, affect the liver and as a group generally tend to have narcotic properties and affect the central and peripheral nervous systems. They can affect other organ systems as well, but particularly the liver so that a "classical" clinical syndrome for toluene might include a cracking of the skin, central nervous system depression, fatigue and dizziness and possibly liver enzyme changes.

A heightened level of consciousness of the possibility that environmental factors might be closely related to disease is critical to considering the "disease syndrome". During an evaluation and examination of a group of workers heavily exposed to chlorinated hydrocarbons medical records of evaluation and treatment by physicians who saw them during the first year following exposure were reviewed. Some had been diagnosed as having skin problems by a dermatologist, bladder problems by a urologist, hepatic disease by an internist and acute depression and anxiety by a psychiatrist. There was no intergration of these organ diseases into what was clearly a clinical syndrome resulting from exposure to a toxic agent.

It would seem appropriate to end this presentation with some recommendations in addition to those already made, for future activities in environmental medicine. The first is to qualitatively increase the didactic and clinical offerings in occupational and environmental medicine to medical students and residents in medicine. Continuing education programs for physicians should certainly contain lectures and other educational offerings dealing with the impact of environment on health, with suggestions about expanding the clinical history in office practice to include the work and community environment. This is particularly relevant for those who completed their medical education before it became generally recognized that environmental exposures were often causally related to clinical disease.

Finally a significant effort should be made to formally train physicians as specialists in environmental medicine. Since occupational medicine is a microcosm of environmental medicine it represents a discipline where such training is already being carried out. Until the development of the NIOSH educational resource centers, less than 700 certified physicians were practicing occupational medicine as a speciality and of those less than 200 received formal training in this specialty. Physicians trained in occupational medicine are required to develop skills in environmental health, biostatistics, epidemiology, and toxicology and to have some knowledge of industrial hygiene and industrial process. Physicians seeing individuals with diseases that could or might be environmentally related will attempt to answer questions such as:

1. Is the temporal relationship of exposure to developing pathology reasonable and logical?

2. Was the dose of the toxic material sufficient to cause the pathology?

3. Are measures of body burden in the range where disease is known to occur?

4. Is the pathology of the nature of what would be expected of this material?

5. Have other diseases that might cause the same pathology been ruled out?

6. Are those in the population expected to be at higher risk the ones who develop the disease?

7. Are others similarly exposed, similarly affected?

In a paper appearing in January 1971 (Arch. of Internal Medicine, Volume 127) on air pollution and physician responsibility, Carnow stated:

1. The physician should become knowledgeable regarding the relationship of environmental factors to disease.

2. The physician should search for clues to the environmental-disease relationship in the clinical patterns of disease so that definitive epidemiological studies can be carried out as extensions of these clinical findings.

3. The physician should support and participate in studies searching for the complex physical, biological and psychosocial etiologic factors in the changing patterns of disease morbidity and mortality by coupling medical insights with computer technology.

4. The physician should intensify research into the nature of man's interaction with his ecologic system as it relates to health and disease and lend support to the training of physicians who will become environmental specialists and develop this new discipline. These experts can then with engineers, biologists, ecologists, and others of like disciplines assess the health consequences of social and environmental changes and based on a cost benefit analysis (the cost to health as compared to the benefits and comforts given to man determine the value to man of these changes).

5. The physician should develop a therapeutic approach which will consider and utilize environmental etiologic factors. The evidence presented suggests that some high risk groups are already known and have been isolated. These are particularly the very young, the

> poor, and the older age groups with chronic heart and lung disease and those with asthma. Thus evaluation of a chronic bronchitic or cardiac patient should consider the risk factors including disease severity, pollution hypersensitivity, and the general degree of environmental degradation. This would enable the physician to classify the patient as to degree of pollution risk and to use this as a guide for regulating activity and medical dosage in relation to pollution levels. Individuals found to be environmental hyperreactors might even be advised to leave communities where pollution frequently achieves high levels.

Finally, we cannot procrastinate with pollution as we did with cigarettes, where our timidity has cost many thousands of lives. Physicians must become involved and begin to deal with the extremely complex problem of assessing the degree of environmental deterioration which has occurred along with its impact on health. We must begin to grapple with ways to structure a viable environment for future generations. We must see to it that our organizations are intimately involved in a positive way with these and other major problems of our times. Members of the medical profession must give time and energy to serve on legislative and advisory councils, committees, and boards in order to assure that human health will be a major consideration in the deliberation of engineers and legislators in defining legislative needs. Never before has society presented the physician with so wide a field of activity and with so much opportunity to play a key role. This is the time for the physician to become the asklepios politkos visualized by Plato.

Given the enormous toxic waste problems we now face and the increased community awareness and concern regarding the impact of environmental contaminants on health this course of action is even more relevant today than it was a decade ago.

DEFINITION OF ENVIRONMENTAL DISEASE - Caused by toxic chemical or physical or biological agents in the workplace present at a level or under circumstances which permit undue absorption into the body causing and altered cellular and organ response which adversely affects organ function and as a result the health of the persons involved.

PROBLEMS IN DIAGNOSIS

a) Multifactorial.

b) Long latency and low level long term development of chronic disease. Rarely acute.

c) Irreversibility.

d) Unlike occupational exposures - different physicians seeing individuals affected with different diagnoses.

e) Multiple sources of single agents.

f) Multiple substances impacting on a single target organ.

g) Inability to use epidemiology in the classic sense for the single or few cases.

DIAGNOSIS OF CAUSE - Based on level of probability.

How is this Done? By considering major factors relating to ABSORPTION - RISK - EFFECT.

1) Toxicologic assessment - Probability of undue absorption
2) Environmental assessment - Probability of undue absorption
3) Other exposure factors - Probability of effect - risk
4) Biological assessment of those exposed - Probability of effect - risk
5) Biological end point - assessment of effect

TOXICOLOGIC ASSESSMENT

1) Intrinsic toxicity of agent
    a) In relation to other chemicals
    b) In relation to other forms of the chemical

2) Portals of entry of agent and per cent absorbed

3) Form of agent - gas, particle - size, liquid

4) Biological 1/2 life

5) Tissue or organ of storage

6) Known target organ(s)

7) Metabolic products

8) Rates and modes of excretion

ENVIRONMENTAL & INDUSTRIAL HYGIENE ASSESSMENT

Determine:

1) Emission and production data of plants in the area.

2) Changes in processes, materials, controls and when these occurred in industries whose wastes were dumped or which were in the area.

3) Degree of containment through measurements of a) air, b) dust, c) water, and d) soil samples for toxic agents.

4) Probability of containment by noting a) depth of waste burial, b) porosity of soil, c) level of water table, d) packaging of wastes, and e) length of time it has been in dump.

5) Probability of physical contact and entry through inhalation, ingestion or skin by examining:

    a) Availability of water for bathing or drinking
    b) Use of land for gardening, recreation, landfill
    c) Proximity of homes, schools, walkways
    d) Characteristics of climate (e.g. dry, dusty)

OTHER EXPOSURE FACTORS

1) Time of first exposure
2) Duration of exposure
3) Temporal relationship between exposure and disease
4) Other exposures - particularly those affecting same target organ

BIOLOGICAL (HOST) FACTORS

1) Genetic Factors
2) Age
3) Sex
4) Chronic disease particularly of same target organ
5) Habits - cigarettes, alcohol, nutrition

BIOLOGICAL END POINT (HEALTH EFFECT)

1) Measures of body burden (not a measure of effect)
2) History of onset and progression of disease pattern - temporal relationship
3) Physical examination
4) Abnormal organ function - Laboratory and other tests
   - Pathologic specimens

QUESTIONS

1) Is temporal relationship reasonable and logical?

2) Was the dose of the agent sufficient to cause pathology?

3) Is the organ affected and the pathology what might be expected from this agent?

4) Have other agents which can cause the same pathology been ruled out?

5) Are those expected to be at highest risk due to dose or other factors, the ones who develop the disease?

6) Are others, similaly exposed, similarly affected?

Mr. LEVITAS. Thank you very much, Dr. Carnow.

Dr. Karrh, I think it would be well—I just had a discussion with Mr. Molinari about the procedure I announced. Since I take it you will be addressing from another point of view some of the points that Dr. Carnow has made, we will hear from you at this point.

Dr. KARRH. Mr. Chairman, members of the subcommittee, my name is Bruce W. Karrh. I am the general director of medical, safety and fire protection for the Du Pont Co. I am appearing today on behalf of the Chemical Manufacturers Association, CMA, a nonprofit trade association whose company members represent more than 90 percent of the productive capacity of basic industrial chemicals in this country.

We appreciate the opportunity to present our views on the compensation of persons injured by exposure to hazardous substances. This is an important subject and we are taking a constructive role in reaching sound public policy on this issue.

CMA strongly believes that individuals harmed by exposure to hazazdous substances should be compensated by those who have caused their injuries. We are concerned about anyone injured from such exposures, and we support the right of an injured individual to receive fair and speedy compensation. However, as I will discuss, we have not seen evidence of a significant health problem from hazardous wastes. We fully agree that concerns in this area require a thorough scientific review, but we also believe that in view of the review processes now moving forward, it would be precipitous for Congress now to enact pending proposals to modify existing compensation systems.

Compensation for nonworkplace injuries traditionally has been handled through the common law tort system of the various States. It has recently been asserted, however, that new approaches are needed because the existing tort law system is inadequate to deal with waste site injuries.

These assertions are based on the assumption of a major public health problem from waste sites. Proponents of this view have assumed that large numbers of people are being harmed by waste sites and that the existing legal system will not be able to handle massive numbers of claims to provide redress to those injured. However, this fundamental assumption of widespread harm from waste sites has not been closely examined.

Last year we created a special work group to determine if there was a relationship between waste sites and widespread harm. I served as chairman of this work group. We found that claims of such a relationship run counter to the experience of CMA member companies. Moreover, independent epidemiological surveys have failed to detect significant health problems.

In my testimony today, I will share information that led CMA to this conclusion. I also will describe what CMA is doing to increase our knowledge about potential health problems resulting from waste sites, and in particular I will report on two recent developments which should provide needed data and analysis upon which more informed judgments can be made in the future.

In our consideration of the issue, we found only two valid epidemiology surveys of populations relative to waste disposal sites.

Mr. MOLINARI. Might I interrupt for a second?

Is it your intention to read verbatim the report and testimony you have submitted?

Dr. KARRH. It is my intention to read my oral testimony I have here, Congressman.

Mr. MOLINARI. Are you going to be addressing in your statement the concerns raised by Dr. Carnow?

Dr. KARRH. I had not planned to in my oral statement. I would be glad to respond to questions. I did not know what statements Dr. Carnow was planning to make prior to the hearing, so I could not be prepared to address those.

Mr. MOLINARI. Well, Mr. Chairman, I thought that Dr. Karrh was going to review the statements made by Dr. Carnow and perhaps add to those by his own experiences. And, Mr. Chairman, we have a copy of the testimony here. We have had an opportunity, ourselves and our staff, to read it.

Subject to the biddings of the Chair, I would like to get into specific discussion between these two gentlemen so we can see where there are areas of agreement and disagreement, and then go on from there. We have the testimony.

Dr. KARRH. Mr. Chairman, I would like to respond by reading a paragraph out of your letter to me requesting me to testify.

Mr. LEVITAS. Yes.

Dr. KARRH. And show that I am trying to respond to what I was asked to do.

Mr. MOLINARI. You have responded. I am not suggesting you are not responding. Your response has been received by the subcommittee. We do have a copy of it before us. I think it is comprehensive. You are reading a digest of what you have said in this prepared report.

Now, if you want to continue, I have no objection to it. I just thought we might save time and get into the area that I would like to see us get into. If you prefer to read it, go ahead.

Mr. LEVITAS. What is your preference, Dr. Karrh?

Dr. KARRH. Naturally my preference is to continue as I was prepared to proceed.

Mr. LEVITAS. Then you may proceed in that fashion.

Dr. KARRH. The second study that we looked at investigated the health effects, on the general population, of chemical exposure in highly industrialized Contra Costa County, CA.

This 4-year study, which was conducted by the California Health Department cancer epidemiology unit, was financed by both State and Federal funds. It found that smoking, and not air pollution or chemical exposure at work or from dump sites, was the most likely explanation of higher rates of lung cancer in Contra Costa County.

During the course of the study, we discussed some of the studies that had been done including the studies of the residents in Triana, AL, that were exposed to DDT. CDC could not find any health effects attributed to DDT, but did determine that the residents had absorbed DDT into their system.

These residents have been identified as a group of people that can be studied prospectively, and CDC plans to do such a study to determine if health effects are occurring as a result of the previous exposures to DDT and absorption of the material.

The CMA group I chaired also reviewed a number of studies conducted by the Government and by industry to determine whether occupational exposure to toxic chemicals has resulted in an increased incidence of chronic disease. Based upon our own experience and the available exposure data, we believe that, in general, such employees would have been exposed to higher concentrations of chemicals than the population around waste disposal sites.

Hence, occupational exposure and health data should provide an indication of the health effects that might be expected if similar exposure patterns were encountered by the public. Since we saw no significant increased incidence of chronic disease among employees in the chemical industry, we concluded that widespread increased incidence of chronic disease among the public is also unlikely. Our studies have also found that chemical workers have a lower death rate from cancer and from all causes combined than the general public.

For these reasons, CMA's view is that evidence of a national problem deriving from public exposure to hazardous waste is not at hand. CMA also believes, however, that further scientifically sound information is needed. We also know the public needs reassurance that measures are underway to resolve the questions that have been raised. However, since we have seen no evidence of significant health effects, we have time to do the studies required.

CMA and its member companies are committed to cooperate in efforts to scientifically determine whether and to what extent there may be a relationship between waste sites and illnesses. We have recently undertaken two major efforts to accomplish this.

The first is the successful settlement of a lawsuit brought by the Environmental Defense Fund [EDF] and joined by CMA to get the Government moving on health studies. The second is the completion of a feasibility study on how the best available data and scientific expertise could determine the nature and extent of any such effects.

In section 104(i) of CERCLA, Superfund, Congress called for a scientific program to analyze waste site/disease relationships. Congress also required establishment of a new "Agency for Toxic Substances Disease Registry" to administer this program.

Two years after CERCLA's enactment, the Government had neither established the new agency, nor released significant amounts of Superfund moneys to support the study program by other agencies. It was in light of these failures that EDF and CMA filed their lawsuits.

This important case was settled on May 27. Even before the settlement, the Government had moved to resolve one significant point. On April 25, 1983, the Government formally established the new agency.

The parties then moved quickly to settle the remaining issues. Some of the most important provisions of the consent decree are listed in my testimony and will not be repeated at this time.

Another effort that CMA undertook was the feasibility study that we contracted for in March 1983 with the organization Universities Associated for Research and Education in Pathology. This study has now been completed. It contains important conclusions that bear upon the subject of assessing possible waste site/disease relationships and will be of great potential assistance to the new health agency in carrying out its function. This study was released on July 7, and a copy of the study will be submitted for inclusion in the record of this hearing.

Universities Associated for Research and Education [UAREP] is a consortium of 15 major universities. It was created in 1964 at the request of the National Academy of Sciences and the Department of Defense to do research in the field of human disease.

UAREP has concluded that within 8 to 10 months, it will be entirely feasible to carry out a comprehensive review to evaluate the substantial body of available data for the purpose of permitting an interim conclusion as to the nature of any health effects which may be associated with waste sites.

The objectives of this study are listed in my testimony.

The feasibility study also contains a detailed organizational and procedural outline for carrying out the comprehensive review study. This will require an executive scientific panel, two task forces, and a full-time scientific and support staff secretariat.

CMA is committed to the feasibility study's recommendations to carry out this important and comprehensive review. We believe this study deserves the broadest possible sponsorship and financial support. We are now actively engaged in seeking this support from environmental, academic, Government, and business groups. CMA is committed to beginning this study by September of this year.

Although we have not seen evidence of a significant health problem, and while the limited evidence we have seen makes us believe there is not likely to be a significant problem, we fully agree that the public concern in this area requires a thorough scientific review.

In light of the substantial scientific review processes that are now moving forward, CMA feels it would be precipitous for Congress to enact any of the pending proposals to modify the existing compensation system related to waste sites. These proposals would impose new taxes and establish new bureaucracies, and they tend to ignore established principles of causation. Yet they are based merely on assumptions of need for such measures, and are being proposed at a time when programs are actively getting underway to test such assumptions.

Dr. Carnow mentioned the Black Lung Act. We learned, I think, considerably from the black lung experience. When the legislation was passed, it was estimated there would be 50,000 cases of black lung at a total cost of $500 million. The experience to date has been about 600,000 cases of black lung that have received compensation at a total cost of about $25 billion, and a study by GAO that was recently released indicated that between 80 and 85 percent of these claims were nonmeritorious as far as having disease that was caused by exposure in the mine operations.

In conclusion, Mr. Chairman, I wish to emphasize that we are here to take a constructive role in the process of reaching sound public policy decisions in the public compensation area.

Thank you.

[The statement of Dr. Karrh follows:]

STATEMENT OF BRUCE W. KARRH, M.D., GENERAL DIRECTOR OF MEDICAL, SAFETY AND FIRE PROTECTION, E.I. DU PONT DE NEMOURS & CO., ON BEHALF OF THE CHEMICAL MANUFACTURERS ASSOCIATION

Mr. Chairman, members of the subcommittee, my name is Bruce W. Karrh. I am the General Director of Medical, Safety and Fire Protection for the Du Pont Company. I am appearing today on behalf of the Chemical Manufacturers Association (CMA), a non-profit trade association whose company members represent more than 90 percent of the productive capacity of basic industrial chemicals in this country.

We appreciate the opportunity to present our views on the compensation of persons injured by exposure to hazardous substances. This is an important subject and we are taking a constructive role in reaching sound public policy on this issue.

CMA strongly believes that individuals harmed by exposure to hazardous substances should be compensated by those who have caused their injuries. We are concerned about anyone injured from such exposures and we support the right of an injured individual to receive fair and speedy compensation. However, as I will discuss, we have not seen evidence of a significant health problem from hazardous wastes. We fully agree that concerns in this area require a thorough scientific review, but we also believe that in view of the review processes now moving forward, it would be precipitous for Congress now to enact pending proposals to modify existing compensation systems.

Compensation for non-workplace injuries traditionally has been handled through the common law tort system of the various states. It has recently been asserted however, that new approaches are needed because the existing tort law system is inadequate to deal with waste site injuries.

These assertions are based on the assumption of a major public health problem from waste sites. Proponents of this view have assumed that large numbers of people are being harmed by waste sites and that the existing legal system will not be able to handle massive numbers of claims to provide redress to those injured. However, this fundamental assumption of widespread harm from waste sites has not been closely examined.

Last year CMA created a special work group to determine if there was a relationship between waste sites and widespread harm. I had the opportunity to serve as chairman of this work group. We found that claims of such a relationship run counter to the experience of CMA member companies. Moreover, independent epidemiological surveys have failed to detect significant health problems.

In my testimony today I will share information that led CMA to this conclusion. I also will describe what CMA is doing to increase our knowledge about potential health problems resulting from waste sites. In particular I will report on two recent developments which should provide needed data and analysis upon which more informed judgements can be made in the future.

In our consideratin of the issue, we found only two valid epidemiology surveys of populations relative to waste disposal sites. The first was a study conducted by the New York Department of Health to determine whether the population in Niagara Falls, New York, which could have been exposed to wastes from the Love Canal site, had suffered any increased incidence of cancer. The data employed in this epidemiology study was obtained from the New York Cancer Registry for the period 1955 through 1977. The New York Department of Health concluded that the data showed no evidence of higher cancer rates associated with residence near the Love Canal site than in the entire state outside of New York City. Cancers reviewed included respiratory cancer, liver cancer, lymphoma and leukemia. The only increased incidence noted was for respiratory cancer, but the incidence in the population surrounding Love Canal was not significantly different from the rest of Niagara Falls. Thus, it was concluded there was no evidence that the lung cancer rate was associated with toxic wastes. Moreover, despite earlier assertions, a recently released study by CDC has not found an increase in chromosomal damage in Love Canal residents when compared to residents elsewhere in Niagara Falls. The study reported no increase in abnormalities among residents or former residents of the area surrounding the canal when compared to residents away from the site.

The second study we looked at investigated the health effects, on the general population, of chemical exposure in highly industrialized Contra Costa County, California. This 4-year study, which was conducted by the California Health Department Cancer Epidemiology Unit, was financed by both state and federal funds. It found that smoking, and not air pollution or chemical exposure at work or from dump sites, was the most likely explanation of higher rates of lung cancer in Contra Costa County.

Thus, the only epidemiology studies known to us which scientifically analyzed the effects of chemicals from waste disposal sites in the surrounding community suggest no causal link between proximity to the sites studied and cancer incidence.

We have also reviewed a study of residents living in Hardeman County, Tennessee, who used water from a contaminated aquifer. The study found that blood tests for some of the residents displayed a temporary abnormal liver function which, in most cases, disappeared with the removal of the source of exposure.

We also reviewed a number of studies conducted by the government and by industry to determine whether occupational exposure to toxic chemicals has resulted in an increased incidence of chronic disease. Based upon our own experience and the available exposure data, we believe that, in general, such employees would have been exposed to higher concentrations of chemicals than the population around waste disposal sites. Hence, occupational exposure and health data should provide an indication of the health effects that might be expected if similar exposure were encountered by the public. Since we saw no significant increased incidence of chronic disease among employees in the chemical industry, we concluded that widespread increased incidence of chronic disease among the public is also unlikely. Our studies have also found that chemical workers have a lower death rate from cancer and from all causes combined than the general public.

For these reasons, CMA's view is that evidence of a national problem deriving from public exposure to hazardous waste is not at hand. CMA also believes, however, that further scientifically sound information is needed. We also know the public needs reassurance that measures are underway to resolve the questions that have been raised. However, since we have seen no evidence of significant health effects, we have time to do the studies required.

CMA EFFORTS

CMA and its member companies are committed to cooperate in efforts to scientifically determine whether and to what extent there may be a relationship between waste sites and illnesses. We have recently undertaken two major efforts to accomplish this. The first is the successful settlement of a lawsuit brought by the Environmental Defense Fund (EDF) and joined by CMA to get the government moving on health studies. The second is the completion of a feasibility study on how the best available data and scientific expertise could determine the nature and extent of any such effects.

RESOLUTION OF LITIGATION

In section 104(i) of CERCLA superfund, Congress called for a scientific program to analyze waste site/disease relationships.Congress also required establishment of a new "Agency for Toxic Substances Disease Registry" to administer this program.

Two years after CERCLA's enactment, the government had neither established the new Agency, nor released significant amounts of Superfund monies to support the study program by other agencies. It was in light of these failures that EDF and CMA filed their lawsuits.

This important case was settled on May 27. Even before the settlement, the government had moved to resolve one significant point. On April 25, 1983, the government formally established the new Agency.

The parties then moved quickly to settle the remaining issues. Some of the most important provisions of the Consent Decree are as follows:

Registries.—By May, 1984, the Agency must conduct a peer review on the methods to be used in establishing registries of persons who have been exposed to toxic substances. The Agency is required to establish and maintain registries whenever inclusion of such persons "would be scientifically appropriate or valuable for long-term follow-up or specific scientific studies." The Agency must also recommend methods for establishing registries of serious diseases by November, 1983.

Inventory of literature.—By November, 1983, the Agency must establish a "publicly accesible" inventory of literature, research, and studies on toxic substance health effects.

Survey and screening programs.—Based on the registries and other information gathered from the Consent Decree implementation, the new Agency must conduct periodic survey and screening programs "to determine relationships between exposure to toxic substances and illnesses."

Mr. Chairman, I am thus happy to report that as a result of the joint efforts of environmental and industry groups, the important scientific study program called for by Congress in 1980 will now get underway.

COMPLETION OF UAREP FEASIBILITY STUDY

I am equally pleased to report that a feasibility study that we contracted for in March of 1983 with the Universities Associated for Research and Education in Pathology (UAREP) has been completed. This feasibility study contains important conclusions that bear upon the subject of assessing possible waste sites/disease relationships, and will be of great potential assistance to the new health Agency in carrying out its functions. This study was released on July 7, and we have submitted a copy for the record of this hearing.

UAREP is a consortium of 15 major universities. It was created in 1964 at the request of the National Academy of Sciences and the Department of Defense to do research in the field of human disease.

UAREP has concluded that within eight to ten months, it will be "entirely feasible" to carry out a comprehensive review to evaluate the substantial body of available data for the purpose of permitting an interim conclusion as to the nature of any health effects which may be associated with waste sites.

Such a study would have, among others, the following objectives:

To identify those chemicals associated with waste sites which could prove hazardous to humans as the result of excessive exposure;

To identify, if possible, the levels of human exposures likely to occur in association with waste sites;

To define and classify the probable health effects, if any, likely to occur in association with waste sites;

To identify the clinical and laboratory end results that would be useful in investigating problem sites; and

To identify the epidemiological criteria necessary to establish causal relationships.

The feasibility study also contains a detailed organizational and procedural outline for carrying out the comprehensive review study. This will require an Executive Scientific Panel, two Task Forces and a full-time scientific and support staff secretariat. The Executive Scientific Panel will consist of twelve to fifteen eminent academic scientists of international reputation from a variety of relevant disciplines. The task forces will also be staffed by experts qualified to deal with the needed health and environmental reviews.

CMA is committed to the feasibility study's recommendation to carry out this important and comprehensive review. We believe this study deserves the broadest possible sponsorship and financial support. We are now actively engaged in seeking this support from environmental, academic, government and business groups. CMA is committed to beginning this study by September of this year. While the costs of such a study will not be insignificant, we are convinced that the costs will be well worth the benefits to public knowledge and understanding.

Although we have not seen evidence of a significant health problem, and while the limited evidence we have seen makes us believe there is not likely to be a significant problem, we fully agree that the public concern in this area requires a thorough scientific review. In light of the substantial scientific review processes that are now moving forward, CMA feels it would be precipitous for Congress to enact any of the pending proposals to modify existing compensation systems related to waste sites. These proposals would impose new taxes and establish new bureaucracies, and they tend to ignore established principles of causation. Yet, they are based merely on assumptions of need for such measures, and are being proposed at a time when programs are actively getting underway to test such assumptions.

CONCLUSION

In closing, Mr. Chairman, I wish to emphasize that we are eager to take a constructive role in the process of reaching sound pubic policy decisions in the compensation area.

Mr. LEVITAS. Now Dr. Riordan, we would like to hear from you.

Mr. RIORDAN. Good morning, Mr. Chairman. I am happy to be here before you with my colleagues from EPA. In the interest of time, I will restrict my comments to a very brief summary of my written statement. I would also request that you accept for the record the copy of the earlier testimony given before Congressman Florio's subcommittee by EPA's James Barnes, having to do with the issue of toxic victim compensation.

Mr. LEVITAS. Without objection, it will be made part of the record.

[The statement referred to follows:]

STATEMENT OF A. JAMES BARNES, ACTING GENERAL COUNSEL, U.S. ENVIRONMENTAL PROTECTION AGENCY

Good morning Mr. Chairman and members of the Subcommittee. I am Jim Barnes, Acting General Counsel of the U.S. Environmental Protection Agency. I welcome the opportunity to appear before you today to discuss toxic victim compensation and the proposals aimed at addressing it.

The issue of victim compensation goes well beyond EPA in terms of impact and meaning, as it also relates to a multitude of issues, including health-related costs and income maintenance. In recognition of this, and to coordinate Administration efforts and to develop an Administration position, the President has designated a high level Cabinet Council Working Group, under the auspices of the Cabinet Council on Legal Policy. One of the major functions of this Working Group is to review the legislative proposals in the victim compensation area as they relate to existing tort law and existing compensation schemes, such as Black Lung and Social Security. As part of this effort, EPA is working closely with other Federal agencies to consider issues with government-wide implications. This effort will require some time; however, it is driven by the realization on all our parts of the urgent nature of the possibly unfilled needs of those affected by toxic exposure.

Those who suffer debilitating disease from hazardous substance exposure obviously face serious physical, financial and emotional difficulties. We at EPA, and especially those who work to clean up high priority Superfund sites, are familiar with the ways hazardous substances can contaminate our environment by affecting the water we drink, the air we breathe, and the homes we live in. Of additional special concern are the anxieties and fears concerning possible health effects caused by exposure to hazardous substances. At EPA, we believe it is extremely important to provide accurate environmental and health risk information to the residents of areas where exposure to hazardous substances may have occurred. Indeed, openness about what we know, what we suspect, and what we do not know regarding the risks of injury and disease in these situations is perhaps the most important single factor in assisting individuals to cope effectively with the exposure. Ironically, it is this very area of the relationship between exposure and injury where we have the most uncertainty, and it is this uncertainty that is the major cause of frustration when the victims attempt to obtain compensation for their injuries.

EARLY LEGISLATIVE CONSIDERATION OF VICTIM COMPENSATION

In 1980, the Congress considered including provisions for compensation for personal injuries in the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, also known as the "Superfund." It was decided, however, that the initial legislation would involve a Fund to pay the costs of cleaning up releases of hazardous substances and to compensate claims arising from damage to natural resources. Nevertheless, the sponsors of Superfund agreed that there was a need for more information regarding injuries to persons from exposure to hazardous waste. This, in order to provide some of the data and studies that would be needed for future consideration of personal injury-related issues, the Superfund legislation required that, under Section 301(e), a study be conducted of the adequacy of the legal remedies relating to injuries and damages from hazardous wastes. The results of that study have been available for approximately one year and form the basis for a number of legislative proposals currently being considered.

While the analysis of the legal issues has been extensive, I feel that there are other issues which are equally, if not more complex, and require equally thoughtful attention and analysis. All of the victim compensation proposals which are being considered rely heavily on an amdinistrative compensation system to relieve the inadequacies and cumbersomeness of the judicial system. However, we must carefully consider the need for and the feasibility of the administrative schemes and whether the scientific knowledge necessary to implement them is available.

GENERAL SUMMARY OF MAJOR VICTIM COMPENSATION PROPOSALS

The purpose of all these proposals in to improve the chances for recovery for injuries resulting from exposure to hazardous substances. All the bills provide compensation for personal injury resulting from exposure to a range of hazardous substances. Some bills also allow compensation for economic loss or natural resource damage.

All of the bills set up an administrative compensation program to handle victims' claims with payments from a fund. Some rely on extension and/or expansion of the Hazardous Substance Response Trust Fund established under CERCLA while others would create a Toxic Victim Compensation Fund through loans from the Hazardous Substance Response Trust Fund and transfers from the U.S. Treasury, when required. Money for the Fund may be obtained through recoveries from liable parties. H.R. 2582 sets up a separate Victim Compensation Fund with essentially the same tax base and the same tax rate as the Hazardous Substance Response Trust Fund. Most of the bills allow either judicial action or administrative claims, or both, as a forum for relief. Most of the bills would drastically reduce the burden of proof on claimants to establish their injury and its cause. In general, they would require three major findings to establish presumption of injury: (1) that there was a release of a hazardous substance(s) and that the claimant was exposed; (2) that the claimant was exposed for a duration and at a level that is reasonably likely to cause or contribute to claimant's injury; and (3) that it is reasonably likely that such exposure caused or significantly contributed to the type of injury alleged.

There are two types of scientific analyses that responsible agencies may have to prepare. One type is incident specific investigations to evaluate individual claims. The second type of scientifc analysis requires assessments of the health impacts of specific hazardous substances, levels of exposure that would result in specific injuries, and associated levels of risk. As such assessments are completed they would serve as a basis for determinations in claims.

ISSUES RAISED BY THE PROPOSALS

We are carefully reviewing the victim compensation proposals introduced in this Congress. While EPA is not ready to take a position today, I would like to comment on some general issues that we believe we all need to address with respect to various victim compensation proposals.

At the outset, I should note that compensation programs such as the ones proposed by these bills involve many issues other than environmental considerations. We need to determine how such schemes will affect existing systems of compensation, particularly tort litigation. It has been suggested, for example, that the presumptions and evidentiary standards that may be part of a compensation system will eventually be incorporated in our tort litigation system; we obviously must consider the full implications of such a development. We also will have to consider the long-term fiscal implications of compensation programs. Experience with many government administered compensation programs has been that they have grown far beyond initial expectations; we must consider what we realistically can anticipate in terms of growth, both as to claimants and overall cost. We must carefully consider the administrative mechanisms for awarding compensation, and whether these mechanisms actually accomplish the ends sought, and at what costs. In evaluating the costs of compensation systems, we must consider the role of the legal profession and the portion of the compensation that would go toward payment of legal fees. We must also look at the economic consequences of compensation programs, and at who will bear the ultimate costs. And, we must consider how any compensation program relates to other compensation programs already provided by the Federal and State governments, including Social Security disability insurance, medicare/medicaid, and other forms of income maintenance.

These are all issues which go well beyond this Agency's mandate of environmental protection, and necessarily involve other Federal agencies and other Federal programs. In this regard, I would note that the Federal government has considerable experience with compensation programs, including the Black Lung miner's compensation program, Social Security disability insurance, and the Federal employee's and the longshoremans' compensation systems. There are valuable lessons that have been learned with regard to compensating individuals for injuries and illnesses, and we must look carefully at our experiences with these programs in determining whether a particular compensation program is warranted, and, where it is, how it should be structured.

The considerations I have identified above are but a few of the larger policy issues that will have to be dealt with in reviewing compensation proposals. These issues, and the many others we will have to consider, cut across the responsibilities and expertise of many Federal agencies and many Federal programs. As noted in the recent editorial in the Washington Post of this past Saturday, the issue of creating a compensation system involves much more than just determining the best environmental policy, and must be considered in this broader context. For this reason, the Administration has created the high-level interagency Working Group, referred to earlier in my testimony, that will review the broader implications of compensation systems, and the basic questions of social equity at issue.

I also wish to touch on four additional general issues that are particularly important to EPA: first, the scope and definition of the problem; second, the scientific and administrative issues which we must come to terms with in any victim compensation scheme; third, the potential impacts on EPA programs; and finally, the implications of the various funding mechanisms.

A basic question which many people raise with regard to toxic victim compensation is: what is the extent of the victim compensation problem? How many people are injured, what injuries do they suffer, and what and how many substances cause those injuries? Currently, the Agency is assessing the data we have to contribute to answering these questions.

In further viewing this issue, the complexity of defining the problem and its scope must be considered.

Toxic victim compensation has been most broadly defined to cover any injury or disease or death caused by any exposure anytime to any substance any place. On the other hand, it has also been limited to compensation for the injury, disease or death of any person due to exposure to hazardous waste not occurring in a workplace.

A number of questions arise in exploring the definition of toxic victim compensation; to follow are but a few of the most critical. For example, do we agree that only non-workplace exposures are intended to be covered, or would there be instances where occupational exposures should be included? Does "exposure" cover exposure only to hazardous wastes or does it extend to any release of a hazardous substances? Does "hazardous substance" cover only those substances traditionally found in waste sites, or does it extend to the broad range of substances (including those regulated under other laws) in the air, water, drinking water, and consumer use? What more need we know about possible mulitple causes of some conditions that may be linked to exposure to toxic substances? What harms (i.e., death, injury, illness) are to be covered or compensated as a "toxic tort"? Should the proposals only address chronic, but not acute, health effects? What is the relationship of this type of action to product liability law?

The scientific assumptions and requirements which underlie all the victim compensation proposals are among the most important issues in the whole victim compensation area. All victim compensation proposals assume some ability through science to establish a cause and effect relationship between particular substances, exposure levels, and diseases. This may not be the case. We must look closely at the questions we are asking scientists in these proposals, to assess whether or not the ability to implement the legislative scheme exists.

In addition, although EPA has extensive experience regulating toxic chemicals under RCRA, FIFRA, TSCA, the Clean Air Act and Clean Water Act, the case specific scientific analyses and conclusions required in the proposed legislation differ significantly from our experiences with existing laws. The scientific data and analyses that would be required to answer the questions above may not currently exist. We intend to assess the ability of the Agency to gather such data and answer these questions. We must assess the scientific feasibility of implementing these potentially broad statutory requirements. Some of the proposals, including H.R. 2582, require the Federal agency, either EPA or HHS, to produce toxic substance documents. We are attempting to assess the magnitude of these requirements, but based on EPA's experience, these documents could be very costly and each one could take up to several years to complete.

A third area of concern for EPA is the possible impact of victim compensation proposals on existing programs and what the possible effect might be on our ability to carry out current responsibilities. Assigning a regulatory agency such as EPA responsibility to compensate people for injuries due to environmental exposure to hazardous substances might well create serious conflicts with EPA's existing responsiblities to regulate environmental contamination under the many statutes the Agency administers and to respond to hazardous substance releases under Superfund. Furthermore, EPA is not involved in administering any programs of this nature and therefore, all its administrative implications would require further analysis. Other agencies with expertise in this area might be able to provide valuable information to the Congress.

Implementation of Superfund is exemplary of this issue. Victim compensation claims and Superfund response actions could exert significant influence on each other. In making decisions related to taking response actions, the Agency gathers extensive data about a site and determines the most cost-effective response that mitigates any public health or environmental hazard. The data required to make these determinations may be very different from data the Agency would collect to assess victim compensation claims. Similarly, the Agency might decide that the appropriate response would be site closure and permanent relocation of residents without extensive cleanup or study of the area. Detailed health assessments would require much more extensive work, and expenditures from the Fund, than would be taken in solely a response action. This competition of interests and purposes between victim compensation and cleanup needs must be assessed before decisions are made with respect to appropriate legislation.

Finally, the proposals contain some variation in funding mechanisms. It is critical that we determine whether the funding mechanism is viable and funding levels are adequate to pay claims. An additional funding issue relates to the CERCLA Post-closure Liability Fund. CERCLA established the Post-closure Liability Fund to assume virtually all liability, including for personal injury, and for certain eligible closed land disposal facilities which operated under final RCRA permits. H.R. 2582 sets up a Post-closure Victims Fund which duplicates the Post-closure Liability Fund both in purpose and in tax base. Both Funds would apparently exist side by side with some inconsistencies and differences which would be unresolved by the proposed bill.

EPA EFFORTS IN THIS AREA

Faced by the urgency of some of the issues in this area, EPA has undertaken to further analyze and better understand this critical area. Accordingly, we have commenced a review of legislative proposals focusing on administrative and scientific issues as well as assessing the impacts upon the Agency's substantive programs and its resources.

An important issue that we are investigating is EPA's ability to conduct the kinds of health effects studies required by the various legislative proposals. Our ability to develop these studies relates directly to our capability to answer the scientific questions I highlighted earlier in my testimony.

WHAT LIES AHEAD

The Congress faces a substantial undertaking in considering the range of toxic victim compensation issues. At this point, the only conclusion that is clearly evident to me is that we all share a large degree of concern for the victims of hazardous substance exposure, and we at EPA stand ready to assist you and them in any way possible.

Adequate consideration of the full range of toxic victim compensation issues will require coordination, cooperation, and good will within EPA, the Executive Branch, and between the Congress and the Administration as well as with the States, which have a great interest in what is finally decided here in Washington.

It is certainly worth the effort of us all to assure that all parties with an interest in this issue are heard during the Congressional deliberations which will follow today's hearing.

We at EPA pledge to do what we can to assist in this important effort and will keep this Subcommittee and Congress apprised of our activities as well as progress toward the goal of developing more scientific certainty in the area of health effects resulting from exposure to hazardous substances.

This concludes my prepared statement. I would be happy to respond to your questions.

Dr. RIORDAN. I have with me Dr. Betty Anderson, head of the Office of Health and Environmental Assessment. That office has the responsibility for providing guidance on carrying out risk assessment as well as actually carrying out risk assessments in the agency. To her left is Dr. Casey Jason, a medical officer and expert in pediatric risk assessment, and Dr. Lewtas, who is head of the Genetic Bioassay Research Branch of EPA's Health Effects Research Laboratory at RTP and is prepared to answer questions on our research program. We are hoping to elucidate on the problem of risk assessment in the future.

I would like to start off by saying we do carry out risk assessments in EPA for the purpose of setting regulations and standards. We have been involved in this activity for several years. I think that the methodologies that we have adopted have met the test of legality. They have met the test of science and they have met the test of policy. However, I would like to elaborate a bit on the risk assessment activities, so that I don't provide you with a misapprehension that risk assessment may be terribly useful in terms of implementing a toxic victim's compensation program.

The utility of risk assessment has been demonstrated but the efforts have only been able to give us crude indicators of potential adverse effects and the extent within the population. They do not pinpoint in any specific way whether ill effects will occur and, if so, in which exposed persons they will occur, nor do they allow for an increase expected by chance alone in the population based upon a sample study.

Present risk assessment activities in EPA have centered on analysis of single chemicals. The difficulties there are less than they are from chemical mixtures such as diesel emissions.

When we come to hazardous waste sites, we have multiple problems in performing and interpreting risk assessments. There are potentially thousands of waste sites nationwide, each containing hundreds of possible different chemicals.

I would like to briefly refer to Love Canal to demonstrate the problems that we face. It is illustrative because of the great number of substances that might be involved in a particular site. With Love Canal not only do we still have some incompletely described compounds in terms of their health effects but even those for which we have health information, the data are limited. Well over 400 substances were found to be present in Love Canal.

I would like to say that in those substances that were found at Love Canal, just to give you an idea of the problems that are involved, of the 400-plus compounds found in Love Canal, following analysis, 10.8 percent were tentatively classified as mutagens, 12.8 percent as carcinogens, 7.2 percent as fetotoxic, 5.8 as neurotoxic, 9.7 percent as hepatoxic, 9.5 percent as renal toxicants, and 8.6 as pulmonary toxicants, from animal and *in vitro* tests.

We have heard earlier testimony by the second witness that it has been very difficult to find any effects in the Love Canal population as a result of epidemiological studies. There is one study that is yet to be published in the peer reviewed literature which does indicate an impact on birthweight of children born in what we call the wet areas in Love Canal.

But the problem with that study is although we get a statistically significant relationship with low birthweight from the babies born in the wet areas of Love Canal, it is difficult to interpret what that statistically significant increase in low birthweight means in terms of potential health effects. So even when you come out with a study which identifies an indicator effect, it is hard then to relate that to some hard effects that might be at discussion in a victims compensation proceeding.

It is very difficult, given the multiple chemicals and given the multiple sites that one deals, to develop a risk assessment that would be useful in the victims compensation area.

I would simply like to close, then, by saying that we have risk assessment procedures that we use in setting standards and regulations in EPA. They essentially provide us with rough indicators of potential effects on a statistical basis in an exposed population.

If we examine the underlying science behind those procedures, they would not probably hold up very well in a cause-and-effect relationship determination that is necessary, in what we would expect to find in these proceedings for toxic victims compensation. I won't get into some of the details.

I think the initial witness elaborated quite a bit on the scientific questions that have to be addressed in that kind of a proceeding. We are here I think to answer questions that might help you in understanding some of our experiences.

Thank you, Mr. Chairman.

[The statement of Mr. Riordan follows:]

STATEMENT OF COURTNEY RIORDAN, ACTING ASSISTANT ADMINISTRATOR FOR RESEARCH AND DEVELOPMENT, U.S. ENVIRONMENTAL PROTECTION AGENCY

Good morning, Mr. Chairman and members of the Subcommittee. I am Courtney Riordan, Acting Assistant Administrator for Research and Development of the U.S. Environmental Protection Agency. I welcome the opportunity to appear before you today to discuss scientific and health research issues which relate to the problem of toxic victim compensation as well as EPA's current research work.

On June 29, 1983, Jim Barnes, Acting General Counsel of EPA, appeared before Chairman Florio's Energy and Commerce Subcommittee on Commerce, Transportation and Tourism to discuss the general issue of toxic victim compensation. In his statement, Mr. Barnes indicated EPA's and the Administration's concern for those exposed to or living in areas subject to the potential risks due to hazardous substances and outlined our efforts to address this critical issue. Additionally, he discussed a number of concerns we have regarding various proposals in this area—including concerns relating to science and health issues. I respectfully submit to you a copy of Mr. Barnes' statement and request that it appear as part of the record of today's hearing.

I share Mr. Barnes' concerns over the plight of those exposed to hazardous substances as well as those who live in areas faced with potential hazard. I feel that it is important that we in government—at all levels—do what we can to inform and, if necessary, assist those faced with the likely or potential effects of toxic exposure due to improper use, release, or disposal of hazardous substances.

A critical part of any attempt to consider this multi-faceted problem is to understand the current state of scientific knowledge and efforts to obtain adequate scientific data and appropriate methods for useful analysis. I should note at the outset that EPA is but one government agency involved in this area. For example, EPA's "Superfund" statute assigns to the newly created Agency for Toxic Substances and Disease Registry responsibility for health monitoring and health assessments. EPA is also working closely with States, and in particular State Health Departments, on these matters.

In my statement, I will first discuss EPA's risk assessment activities under our existing statutory mandates. Second, I will address a number of the key scientific issues which must be considered when examining the various proposed compensation schemes, including: exposure, likelihood of injury, and causation. Finally, I will outline the research efforts currently underway involving EPA which may offer some assistance in this area.

RISK ASSESSMENT IN EPA

Within the federal government, EPA's risk assessment responsibilities are unusual in that they emphasize assessments of health risks for regulatory decision making. The manner in which risk assessments are used depends upon the statutory provision being implemented. By contrast, the National Institutes of Health, for example, and within it, the National Institute of Environmental Health Sciences, places a much greater emphasis on basic research. These entities do not have regulatory responsibilities. Although the EPA conducts research and risk assessment in many health areas, our cancer risk assessment approach provides insight into the complexities and limitations of performing risk assessment generally.

In assessing the possible risk of carcinogens posed by individual chemical substances, EPA follows a two step approach. Risk assessment attempts to answer two questions: 1) how likely is the event to occur? 2) on the assumption that the event does occur, what is the magnitude of the public health impact? Since only rarely do we know for sure that an agent is indeed a human carcinogen, the first step involves an evaluation of all the biomedical data to determine the weight-of-evidence that an agent might be a human carcinogen. The second step involves the quantification of risk, that is public health impacts, in terms of rough estimates for current exposures as well as estimated exposures for various regulatory options.

To answer the first question regarding likely carcinogenicity, EPA weighs the biomedical evidence as ranging from the strongest evidence based on human data, backed up by animal bioassay tests; to suggestive or supportive evidence provided by positive results from short-term in vitro test. This weight-of-evidence is described in terms of the nature of the responses, the quality of the data, and an evaluation of both positive and negative results.

The second step, that of presenting some quantitative estimates of public health impacts, is presented in terms of rough estimates describing the individual increased cancer risk for exposed sub-population groups, (i.e., increased risk of, for example, one chance in a thousand or 1×10^{-3}) and the nationwide impact in terms of annual increased cancer cases. This second step is intended to give the regulators a feel for the potency of the suspect carcinogen and some rough idea of the magnitude of the public health problem. It seems useful to provide these rough estimates as a measure of potency, because the potency of carcinogens can span a range of fifty million fold. There is an obvious desire to take this disparity into account in making public policy decisions even though scientific methods for precisely describing quantitative risk associated with environmental exposure was and still is a very underdeveloped field. For most suspected carcinogens, there are no methods currently available to accurately describe risk outside the dose range where effects have been bracketed between a plausible upper bound and a lower bound approaching zero. The upper bound is calculated using conservative exposure estimates and the linear, non-threshold dose response model at low doses.

In many ways the approach has worked reasonably well. The qualitative (i.e., biomedical) evidence coupled with quantitative, rough estimates are useful in setting priorities; and balancing risks against benefits, and in considering residual risk after the application of best available technology.

Risk assessment approaches have evolved over the years and will continue to do so. This is a rapidly developing field but there are large gaps in scientific knowledge which must be filled in order to make real improvements in risk assessment methodology.

In short, the utility of risk assessment has been demonstrated in the EPA, but there are many scientific uncertainties associated with risk assessments. Our experience is helping to shape our current research efforts. These efforts are only able to give us crude indicators of potential adverse effects and the extent of harm within a population. They do not pinpoint in any specific manner whether ill effects will occur and, if so, in which exposed persons, nor do they allow for an increase expected by chance alone in a population based sample.

Present risk assessment activities at the EPA, in response to our statutory mandates, have centered upon analysis of single chemicals. The difficulties there are less than they are for chemical mixtures, such as diesel emissions. When we come to hazardous waste sites, we will have multiple problems in performing and in interpreting our risk assessments. There are potentially thousands of waste sites nationwide, each containing literally hundreds of different chemicals. We must determine which chemicals are present, in what concentration, and we must estimate the proportion of chemicals that humans are exposed to and what proportion may enter the body. Existing hazard data on each of the chemicals must be assembled and analyzed to determine if there may be a problem. Exposure and hazard information need to be combined to estimate in some quantitative manner our degree of concern about potential risks. To deal with 400 or more chemicals per site becomes a difficult task, and we really have no means presently of intelligently evaluating possible interactions, for example, synergism among chemicals. Each toxic waste site is a unique microcosm of potentially hundreds of chemicals and spontaneous reaction products. To help illustrate some of the pitfalls in performing assessments at waste sites, let me give some examples.

Love Canal, New York is especially illustrative of the great number of varied substances which might be involved in one site. For Love Canal, not only do we still have some incompletely described compounds but even those for which we have described health information, the data are limited. Well over 400 organic substances were found to be present.

EXPOSURE INFORMATION AVAILABLE TO THE AGENCY

Environmental exposure to hazardous substances outside of the workplace is generally quite low but may be persistent through time. Depending upon where and when environmental sampling is conducted, exposure estimates of varying accuracy may occur. For example, measurements of PCB's dioxins, or metals in the immediate area around dumpsites may be representative of levels which can be used to determine exposure. However, the same may not always be said for volatile organics. Here the transport through the dumpsite and neighboring areas as well as through man may be quite rapid. Thus, in the case of volatile organics, even if a health effect were the result, documenting and quantifying the exposure which may have contributed to this outcome may be difficult if not impossible.

Body burden will be dependent upon more than isolated environmental measurements. It must also take into account specific routes of exposure and habits of certain population subgroups. For example, a child who eats soil might have much higher levels of certain toxic substances than an adult under seemingly the same exposure conditions.

LIKELIHOOD OF INJURY

It is difficult to determine whether exposure to a hazardous substance has caused a particular adverse effect. Of the 400 plus compounds found in Love Canal following analysis, 10.8 percent were tentatively classified as mutagens, 12.8 percent as carcinogens, 7.2 percent as fetotoxic, 15.8 percent as neurotoxic, 9.7 percent as hepatoxic, 9.5 percent as renal toxicants, and 8.6 percent as pulmonary toxicants from animal and in vitro tests. Little or nothing was known about the potential toxic effects of the remaining substances—over half of those found.

Levels of exposure will generally be quite low when compared to animal or even industrial exposure settings. It appears that most health effects resulting from hazardous substance exposure are likely to be chronic effects involving commonly occurring diseases, rather than rare diseases. Thus, it will be necessary to separate increases in various relatively common outcomes from the expected rate. Low birth weight and chronic lung disease, for example, rather than mesotheliomas which can more confidently be associated with a certain exposure to a specific chemical agent.

In order to get an idea of what this means on a site specific basis, we should consider the relevant experiences at Love Canal and Woburn, Massachusetts.

The only study on Love Canal which so far seems to have demonstrated a statistically significant difference between exposed and comparison groups related to birth weight. Low birth weight is strongly associated with major malformations, high neonatal mortality, and development problems. In the surrounding "swale" area a highly signigicant increase in the rate of low birth weight was seen even after correcting for many maternal risk factors, including maternal alcohol consumption, maternal cigarette consumption, and other maternal characteristics. This result is also consistent with the literature on animal embryo toxicity with lower dose chemical and pesticide exposure. However, low birth weight is expected to occur in roughly 6 percent of the white and 12 percent of the black births. In addition, a base line expected low birth weight rate that takes maternal risk factors into consideration, is difficult to establish.

In general, the Love Canal experience is valuable in considering victim compensation issues as it emphasized several important points, including the following.

1. Looking for rate health outcomes probably will not be helpful except in specific circumstances, such as with sufficiently large population groups to be able to detect the event.
2. Looking for an increase in chronic health effects which requires an understanding of the expected rate for a similar unexposed population is much more likely to be fruitful.
3. Exposure types and amounts especially for volatile substances will change through time and will be difficult to document.

Finally, I would also like to offer some comments on Woburn, Massachusetts, a place where a cluster of adverse health outcomes has been seen and evaluated in terms of associated environmental pollutants. This area has also been cited in support of legislation for toxic victim compensation.

In the summer of 1979, the citizens of Woburn, which is located about 12 miles northwest of Boston, became quite concerned over the health impact of 100 years of dumping various arsenic and other compounds in the Northeast sector. The initial concern arose when an apparent increase in childhood leukemias was discovered. In eastern Woburn over the period 1969–1978 a 12-fold increase over the expected rate was seen in childhood male leukemias.

Historically the area of exposure was a leading producer of arsenic compounds from 1900–15 as well as other chemicals and glues. The main route of suggested exposure was through two particular wells supplying drinking water throughout the 1950's through the 1970's. Unfortunately, historical information on drinking water toxic substance content was lacking. The problem was evaluated by the Commonwealth of Massachusetts and the Center for Disease Control and the following conclusions were drawn. Although there was an increase in leukemias around the Woburn area, case-control questionnaire data failed to identify any lifestyle differences among the cases and controls. For the one compound known to have heavily contaminated the area, arsenic, previous human epidemiologic studies have shown increased rates of lung and skin cancer following arsenic exposure but not leukemia. In other words, investigators were unable to discern whether any of the potential chemical exposures could account for the clustering of leukemia cases.

CAUSATION

The above discussion helps to indicate that determining a cause of an observed health effect is a very difficult problem—one with which science is currently struggling. This is especially the case with chronic effects, which are the types we most expect to occur from exposure to hazardous waste sites. Our risk assessments can only give us some rough indications of how much levels of exposure may increase the chance of injury. Applying these kinds of test results to the compensation setting is problematic. In chronic exposure cases, we are usually confined scientifically to determining association of exposure and disease, not causation. Furthermore, we cannot confidently distinguish between individuals in the background population who would develop illness anyway and those whose illness is attributable to hazardous substance exposure.

Problems continue to affect our ability to predict health effects in humans. The scientific community involved in risk assessment is aware of these problems and is continually seeking to improve the state-of-the-art of risk assessment. To summarize, we have a long list of waste sites. Each contains a myriad of hazardous substances that must be identified and quantitated. Not only is our information on health effects limited for many of these substances, but our testing procedures cannot account for multiple risks, synergistic, or antagonistic reactions among chemicals. Second, although a substance may clearly injure both animals and humans, the manifestations of illness may be quite different in humans than in animals. This problem makes human health effects difficult to predict. Third, many chronic health effects occur after years of low-level exposure. Modeling this would be very time-consuming and expensive, so instead we test in a shorter period using large doses. This procedure yields sound information for regulatory purposes, but whether the conclusions are appropriate to decisions that would have to be made in a compensation system is not clear and is, fundamentally, a policy decision.

RELATED RESEARCH EFFORTS

Some of the efforts now underway at EPA which may be of future help to prioritize and evaluate hazardous substance risk include the following:

1. Establishing the expected rates for sensitive reproductive health outcomes in children at the county level.

A. County level: As mentioned before, birth weight is a sensitive indicator of toxic substance effect on animals and as suggested in Love Canal may be a good outcome to assess for humans. We are presently developing national county level birth weight mapping techniques using vital statistics records which adjust for maternal risk factors using specific statistical techniques.

B. Local level: EPA in collaboration with New York State and now with Missouri will be developing a local census tract level assessment of birth weight using similar techniques to those developed at the national levels. In addition, adjusted childhood cancer rates are also being added at the local level. It is hoped that besides a comparison to national mapping techniques, more and better risk factors can be considered to refine the assessment technique and aid in priority setting for dumpsite clean up. Potentially the techniques being developed in these two states could go down to the level of Love Canal areas. This is also being developed to complement ongoing state efforts in this area.

2. Animal/Human Correlation Studies: The currently available animal toxicity information on reproductive problems associated with toxics substance exposure is being compared to all available human data on the same substances to begin to address the problem of generalizing animal study information to human risk assessment.

3. Correlation of exposure induced genetic damage in somatic (body) and germinal (reproductive) cells resulting in heritable changes which might involve risk to future generations of exposed individuals.

4. Significant gaps in the risk assessment methodologies are being addressed along with validation of methodologies. Although past efforts have been essentially limited to cancer risk, we are currently working on both qualitative and quantitative procedures to improve risk extrapolation methods for animals to man for mutagens and carcinogenesis, as well as for potential adverse specific health effects such as: neurobehavioral, pulmonary, hepatic, reproductive, and teratologic. Methodologies to predict heritable genetic effects of chemicals found in the environment will also be addressed.

5. ORD is now verifying a screening test system to evaluate the potential health effects of complex waste mixtures. The proposed program uses in vivo and in vitro assays of increasing complexity to estimate the biological activity of the complex mixture.

CONCLUSION

Adequate consideration of the full range of toxic victim compensation issues will require coordination, cooperation, and good will within EPA, the Executive Branch, and between the Congress and the Administration as well as with the States. Everyone will be affected by what is finally decided here in Washington, whether they be from business or from affected or potentially affected areas.

We all feel a deep concern for the victims and potential victims of hazardous substance exposure. We at EPA pledge to do what we can to assist in this important effort and will keep this Subcommittee and Congress apprised of our activities as well as progress toward the goal of developing more scientific certainty in the area of health effects resulting from exposure to hazardous substances.

It must be understood that science can only provide statistical probability of cause. Given that limitation, it must be left to the policy maker, not the scientist, to decide whether to award compensation.

This concludes my prepared statement. I would be happy to respond to your questions.

Mr. LEVITAS. Let me say this at the outset. I know that members of the subcommittee, myself included, have a large number of questions that we would like to put to various members of the panel. What I intend to do is go through a certain number of questions that I have at the outset, and then pass it along to some of the other members, and then come back around a couple of times, so that we let everybody have an opportunity to begin to focus on some of these issues.

Let me start with Dr. Carnow. In making both legislative decisions or in governmental agencies making enforcement or action decisions, or in litigation, we need to operate on the basis of relating the existence of a phenomenon, namely, a hazardous waste site to reported health effects in a surrounding population.

In your judgment is there reliable evidence upon which either we as legislators or courts or enforcement agencies, regulatory agencies, can operate to relate the presence of a linkage between the existence of the hazardous waste site and the health effects which are reported in the surrounding community, or is it so indefinite that we are not able to make those decisions, based on the evidence available?

Dr. CARNOW. I think in some cases there may be some lack of definition. I think, though, that much can be done. I think using the kind of models that Dr. Conibear and I have developed, for example, might be useful in making an assessment of the probability of causation. One of the problems is that very standard tests are done. Anybody knowing American medicine knows we have many tests for the same thing.

We must have 20 tests to determine whether or not the liver is healthy. The reason that this is the case is because we don't have one single test that tells it all, so we do many. Our tests are also calculated to find overt disease.

Preventive medicine is something which is just coming down the road, so most of the time we look at clinical disease and our tests measure clinical disease. One of the things that we have to do is to address—and some of us have—much more the problem of developing tests which show preclinical disease or subclinical disease. Let me give you one example.

We know that lead will cause a slowing of conduction in motor nerves, and so we began to set levels for safe levels of lead based on that. What was not recognized at the time was that the kidney is the major target organ, and so to a large degree that was ignored.

The second thing that happened is that scientists who were looking for early tests began to look even more carefully, and Dr. Seppalinian found if you looked at slow rather than fast fibers, you could pick up damage at a much earlier point in time. So one of the problems that we have is that the tests that we do may not be sensitive enough. We have to develop more sensitive tests.

The second thing that we need to do is to look at the development of new or extended tests. One of the things that we believe, for example, is that an important early effect of many toxic agents is on the central nervous system, particularly the brain, and we have developed a very extensive, in some cases complex neural behavioral batteries, which we feel can find early evidence of neurological brain damage, so that new tests have to be developed.

The other problem—and you allude to it when you say to reported health effects—is that some of the health effects of toxic agents are not known. It was, for example, thought in relation to dioxin that if you did not have chloracne, which is a disfiguring kind of acne, you didn't have the disease. Well, the problem was that the disease was first looked at by dermatologists.

We now know that very few people exposed to dioxin may develop chloracne, but there may be a wide range of other problems that individuals have, and so the first thing that has to be done is to gather all that is known about the scientific literature about an agent or a group of agents. Then the second thing is, again, to make an assessment of what we don't know about those agents.

For example, we have now examined hundreds of individuals in communities who may have been exposed to dioxin. We find in more than normal numbers individuals with immune deficiencies, which is not a common phenomenon in the general public, of peripheral neurological damage, of central neurological damage, of liver damage, abnormalities of lipid metabolism.

Dr. Karrh noted in Triana, that CDC found no disease. Now, that is in a sense true, but it is not quite true, because they found abnormalities of liver activities in these people, and they did not do a comprehensive examination. It was a survey. We did an examination of some, I don't remember, 25 or 30 people in Triana, and we did find damage. CDC did not report on teen-age males who had female breasts, or teen-age females who had precocious puberty, or other abnormalities.

So, again, I think what has to be done is I think more intensive effort. Again, I don't believe that CDC did a bad thing. They did a survey, and a survey only gives you a certain amount of information. But when you have a group of individuals who may have been eating and drinking DDT for a period of 20 or 30 years, in my opinion that deserves very intensive investigation, and our examinations were quite labor-intensive.

Again, you look for what disease is present, and what organs are affected. When you say do you look to reported health effects, yes, but there may be others which have not been reported, and if you find abnormalities you cannot pass that off because they were not reported.

Mr. LEVITAS. Let me put it in a specific context. Dr. Karrh, in his testimony, says, "We have not seen evidence of a significant health problem from hazardous waste."

Now, at the same time, just taking two specific well-known examples, the Federal Government has spent millions of dollars at Love Canal and at Times Beach to respond to a situation where people in the area of the abandoned hazardous waste sites complained of all manner of health consequences, and in response, a decision was made to spend a lot of the taxpayers' money to do something.

The question that I am interested in, was this simply a political response to quiet down some hysterical housewives in the area, or was it justifiable in terms of scientific information.

Specifically, I know you are familiar with the Times Beach situation. Could you describe what medical conclusions you have drawn from your experience in the Times Beach situation, and was the government response appropriate, or should we have simply said, well, as I read Dr. Karrh, yes, there is a hazardous waste site there, and, yes, you do live near it, and you may have these illnesses. But they are not caused by that hazardous waste site, and therefore the Federal Government, the taxpayers, ought not to be spending these millions of dollars.

Dr. CARNOW. Well, I don't know what CDC has done. They have not discussed any of this with me, certainly, and I am not privy to their activities. I believe that one of the physicians in charge of this activity is a physician who was involved in legal activities in relation to others exposed to dioxin, and who testified and the others that although they had a variety of diseases, none of them could be related to dioxin.

I don't know whether that in any way influenced the conclusion that there was no problem. I can only assure you that I have some 1,000 scientific reprints which represents studies of various kinds in relation to dioxin. We have examined now more than 300 people, none of them at Times Beach. We have not examined the Times Beach folks, but we have examined people who have been exposed to dioxin. I can assure you that it is toxic.

I can assure you that it has caused a wide variety of diseases, and I have 30 years of medical and scientific activity which says that those are related to and caused by the exposure to dioxin.

To find 40 or 50 percent of the people in a community with evidence of neurological damage would be extraordinary in a normal community of particularly young, healthy working people. Again, I think that these are not as great mysteries as we make them to be.

I think the problem with Times Beach is an enormous problem. I think dislocating people, moving people out of town, doing all sorts of things like this is a terrible thing to do, and should not be done without cause. But I think that the kind of study that consideration of such a dislocation demands may not have yet been done in Times Beach.

Mr. Levitas. I throw the question to you, Dr. Karrh. Let me phrase it, if I may.

Dr. Karah. All right.

Mr. Levitas. Based on your professional expertise, and as I read the portion of your testimony I just did, do you believe it was an appropriate decision to move, evacuate Times Beach or Love Canal or any of these sites which are now well known to us, based upon the medical and scientific evidence available, or do you believe the contrary, that it was mostly a political response, not related to the healthy impact on the surroundang community resulting from that hazardous waste site?

Dr. Karrh. Mr. Chairman, I have not studied the people at Times Beach or at Love Canal. As a physician, I have not examined any of those people. I have reviewed the data that are available from those two sites, the data that have been presented both in scientific documents and in the lay press.

Based upon that, it is my opinion, and it was the opinion of my work group that I chaired that was made up of professionals also, that there was not scientific data that these people had health effects that had resulted from their exposure in the Love Canal or the Times Beach area, but that they perhaps had had some exposures that did need further investigation.

I think earlier when you characterized my testimony in your question of Dr. Carnow, I am not sure that your exact statement was what I had said because I have not said that we have a site and we have a disease and the disease is not caused by exposure. What I have said is, based upon the data that we have reviewed, we have not found any valid scientific data that indicates that hazardous waste disposal sites have caused a significant health problem.

We feel, though, that there needs to be more study, and we would hope that people like Dr. Carnow, who are working in this area, would publish their studies so that when we try to pull the data together and determine if we have a problem, and if we do have a problem what is the extent of it, we will have access to those data so we can utilize them in our decisionmaking process.

Mr. Levitas. Dr. Riordan, EPA Is not a think tank. It is a regulatory agency. At Times Beach a decision was made to spend $33 million Superfund money to evacuate that community, buy it out. Yesterday we heard some very poignant testimony about the impact on that community as a result of that decision.

Is EPA in this regard making a political decision in response to the outcries from the citizens and the congressional delegations and the Governor of those affected areas, or is the decision that is made, whether it be Love Canal or Times Beach, made upon a scientific judgment that there is something that is affecting the health of people resulting from that nearby hazardous waste site?

Dr. **Riordan**. Mr. Chairman, I can't speak directly from personal experience, but I think I can speak from being in the agency and being peripherally involved with some of the decisions that have been made at Love Canal and at Times Beach. I would characterize the decision as a prudent public health decision being made in the case of Times Beach. I say that for two reasons, and then I will defer to Betty, if you would like some explanation about some of the risk assessment work that was done as part of the decisionmaking process.

First, the Times Beach situation was somewhat unique in the sense that we had potential for a very ubiquitous exposure to dioxin since the materials had apparently been spread quite widely in the community. It wasn't a contained site where one could perhaps restrict the potential for adverse health effects, but rather it was a potential, extremely ubiquitous contamination, in some cases at fairly high levels of concentration. That led us to be fairly cautious and led us to, I think, decide quickly that we had to take action.

The other thing is that dioxin has the potential for chronic health effects, and although effects at the Times Beach situation may or may not have been expressed as of today, nevertheless the risk assessment activities indicate that in fact long-term exposure may result in some chronic health effects.

That added into the equation, we worked closely with CDC in making that decision. I don't know what levels they were talking about in terms of justification for actual evaluation, but perhaps Betty could fill us in on some of those response studies that were done as part of this.

Mr. **Levitas**. I would like that response, Dr. Anderson, and in addressing it, perhaps you could also answer what I consider to be a simple question. I am sure it is not, but do you consider that there is evidence of significant health problems from hazardous waste sites or not?

TESTIMONY OF MS. ELIZABETH L. ANDERSON

Dr. **Anderson**. To respond to your last question first, in the EPA we have always taken the position that it is our responsibility, as was just said, to pursue a policy that is proven, which means we don't expect to find disease before we act. It is well known that epidemiology methods are not particularly sensitive, and they are expensive to conduct. It takes a very long time, and in some cases is absolutely impossible to identify appropriate cohort groups to study.

So I think from an environmental protection standpoint, we don't look for—you probably heard the term—"dead bodies," before we act. We don't necessarily rely on the human evidence before we take action, but of course, any human data are highly valued and it helps us enormously in making decisions. But I think the whole purpose of the risk assessment in EPA is quite different.

That is, since we don't know for sure what might happen, our purpose is to formulate an approach to taking great uncertainties in the scientific area, and having some consistent way of organizing that information to get some idea how likely it is that disease might occur, and then some feel for if they do occur somewhere down the road from long-term, low-level exposure, what would be the magnitude of the impact.

This has been done in the agency, as Courtney said, I think quite successfully now for the last 6 to 8 years. We have considerable experience in the area of carcinogenesis. There are great scientific uncertainties, there is no question about it.

In many of the evaluations we do, we necessarily have to just take arbitrary positions, because the underlying science is not sufficiently advanced to do anything else. But we think that the fairest thing we can do is to spell out exactly what the basis for those decisions are, and that is exactly what we have been doing.

Certainly these issues are quite debatable in the scientific community. I think to leave any other impression would be incorrect, particularly for purposes of your considerations here.

A risk assessment that would address the issue of whether a person's illness is associated with a particular waste site exposure is different from the risk assessment we have been doing, where we are trying to predict what might happen. Here we want to know the probability that a disease that has occurred is associated with a prior exposure.

I think this becomes even more difficult. That is not to say that one couldn't formulate guidelines for doing it. I think that could be done. I think the guidelines would certainly get into, again, necessarily, arbitrary decisions, necessarily arbitrary rules, and there are going to be enormous data gaps.

For example, we probably would have very little information on what the real exposures had been in the past even if we knew some substances were present, and so forth. I don't know whether this responds to all of your questions here, but I think the flavor of a risk assessment is that when it is predicted, when it is done with nuclear powerplants, when it is done in financial markets, it is much the same. It is a way of organizing great uncertainties, and I think here we are dealing with a very difficult area. That is not to say something couldn't be done.

Mr. **Levitas**. Mr. Molinari.

Mr. **Molinari**. Let me start off by saying that having listened to the testimony of some of those who are victims, outlining the extensive health problems they have had, it is frustrating when you see people who are obviously ill, and there is obviously a connection to a condition of toxic waste exposure. Yet the chemical industry will say there is no scientific evidence to show that in fact those illnesses were caused by dioxin or other toxic waste. It leads me to believe that the attorney who testified yesterday, in suggesting that perhaps we should consider shifting the burden of proof after there is the establishment of an exposure of a serious magnitude, may have correctly identified the way to go.

I would like to just ask you this question, Dr. Carnow. We have a woman who testified yesterday, who had lived in Imperial, MO. She was right across the street from what we call the Minker property, which was contaminated by fill dirt laced with dioxin. In 1982 she went to the St. Joseph Hospital emergency room for bleeding kidneys and bladder problems. She was treated that year for sores that left scars. She had high blood pressure, was told that she had an extremely nervous condition, and was waiting for results from liver and immunity tests.

Her husband experienced swelling of the face, lips, and eyes. For 3 months his eyes were shut at times, originally diagnosed as allergy. In 1982 he completely lost his voice for over 5 weeks and was still hoarse for about 3 months thereafter. Throat continuously sore; bronchial problems.

Ron Jr., 17 years of age when they moved to this site, had respiratory troubles, severe stomach pains, repeated throat infections and colds, viruses, bronchial problems.

A daughter 11 years of age, nosebleeds, cauterization, severe chest pains, shortness of breath, rushed to the hospital with severe stomach cramps. Diagnosed as having hemorrhagic cystitis. Weight loss, the daughter, from 130 pounds to 116 pounds.

Son Ricky, 4 years old, throat infections, medication wouldn't clear it up. Blood clots.

Son Chad, 10 months old, vomiting, diarrhea, stomach problems.

And then interestingly enough, they sell. They get out. The son of the persons who bought the house, a 6-year-old boy, has a kidney problem, and on and on and on.

Now, Dr. Carnow, where you hear these symptoms, and you know that there has been a reported case of dioxin contamination across the street, would you say that there is a very good possibility that these problems, these health problems, have been caused by exposure to dioxin?

Dr. CARNOW. When you have that many people who are sick, and when you have some commonality, like commonality of abnormalities of bloodclotting, which we have also found, and kidney problems which we have known about at least since 1971, because in a horse arena in Missouri, one of the girls and a number of other people who were exposed had that as a first sign, and the 80 horses that died, many of those had hemorrhaging from the urine also, so that you have some kind of commonality. But again the way we would make this kind of a judgment is, first, by taking the kinds of history that you have related; second, looking at the kinds of damage to organ systems that are present in these people, to determine whether those are the kinds of damages that we see in individuals who are exposed, and put these together, because any one of these symptoms can be caused by a number of diseases, and one of the things that is always in contention is does this individual have nine diseases, which are related to one person, or do all of these symptoms and findings put together represent one disease.

One of the great men in medicine, Osler, said many symptoms, one disease. You don't try to make a separate diagnosis for each one. You can say that high cholesterol is due to eating fat and liver diseases are due to alochol and lung problems to smoking; and the kidney problem is common, everybody has kidney problems.

Again, if you see them as separate entities, then you see them as separate diseases. Unfortunately, that occurs. People go to a skin doctor and he says, "Well, you are using the wrong kind of a perfume," and then they will go to a urologist, and so on.

Mr. **MOLINARI**. Let me cut you off, Doctor. If they came to you, would you recommend that they move from the site?

Dr. **CARNOW**. I would recommend that they move from the site, because I know that dioxin is the deadliest chemical known to man. But the second thing that I would do is I would work him up in the way that I said.

Mr. **MOLINARI**. I understand.

Dr. **CARNOW**. And I would make a judgment. But what we are talking about is two things. One, is it safe to stay at Times Beach. I wouldn't go there even for 20 minutes. The second thing is, have these people been affected. I think that in order to make that kind of a determination, you would have to examine them and do the kinds of things that we said. The workups are fairly complex and extensive. If you just do simple tests, you may come away with no answer. I think that that is one of our problems. The workups on these people cost thousands of dollars.

Mr. **MOLINARI**. I understand.

Dr. Karrh, if somebody came to you—and this is not an isolated case; this is just one witness; the others that lived in the Times Beach area had similar symptoms—what would you recommend be done?

Dr. **KARRH**. I think I would take the same approach that Dr. Carnow said. I would like to examine the patients, I would like to talk with them about their symptoms.

Mr. **MOLINARI**. How about the recommendation that they move? Would you join in that recommendation?

Dr. **KARRH**. Based upon the information I have now, no, I wouldn't make that recommendation until I had worked them up and decided whether or not I thought the conditions they had could be related to where they live.

Mr. **MOLINARI**. How long would it take for you to make a determination that there is scientific evidence, as you put it, to indicate that exposure to dioxin was the reason for these people becoming ill?

Dr. **KARRH**. That is a question I don't think any physician can answer, because it depends upon each case and the amount of information you have from that case, and what results you are getting back from the lab tests and other tests that you are doing. But you have to do it based upon scientific determination, not on emotion.

Mr. **MOLINARI**. I understand that. But in the meantime the people are emotional because they are sick.

Dr. **KARRH**. I think we all get emotional when we get sick, yes, sir.

Mr. **MOLINARI**. And some of these nervous problems that people are told they have in fact have been diagnosed by others as not really being nerves. It is a manifestation of the problem. Indeed, it could be nerves, too.

Dr. **KARRH**. Yes.

Mr. **MOLINARI**. Triggered by the trauma that they have in the family and living under those conditions. The point is this: what I see, from what I have heard today, particularly from the chemical industry representative, is that we should not suggest that these health conditions are caused by exposure to known large quantities of dioxin in the area.

We have heard testimony about very small quantities being fatal to animals. Oh, yes, we can say, as the chemical industry will say, there is no relationship. In different animals, it takes different doses to die, and we don't know the human toxicity because we don't inject humans with the stuff to see how much of a quantity it would take to be lethal, if at all.

Dr. **Karrh**. Congressman, I don't think you have heard from the chemical industry today what you have said you heard. I think what you have heard us say is that we have not seen evidence of a significant health problem from hazardous waste. We fully agree that concerns in this area require a thorough scientific review.

We feel we ought to get on with that scientific review both through the efforts of the chemical industry, efforts of people such as Dr. Carnow, and from ATSOR that was set up by Superfund and then decide what types of regulations should be put in place.

Mr. **Molinari**. When did you come up with the decision that this study should be made?

Dr. **Karrh**. This was in my testimony that you objected to me reading earlier.

Mr. **Molinari**. You just made that decision. We just became aware that there could be problems associated with chemical substances? What I am asking you is, why did it take so long for the chemical industry to say we believe a study should be made at a particular point in time?

Dr. **Karrh**. We have been studying the toxicity of chemicals for many years. My own company started a toxicology laboratory in 1935 solely for that purpose, to study the toxicities. I think we only became aware that there could be some health problems in communities as a result of waste disposal sites within the last year or two. The Love Canal situation triggered a lot of the concern, people began to look more, and EPA began to look more.

The chemical industry has had a concern about this for quite some time. The concern culminated in November of last year when the study group, that I chaired, was put together to try to determine what was the extent of the scientific data that indicated that there were health problems as a result of waste disposal sites and waste disposal practices in the past.

We have concluded that we have not seen significant numbers of health problems, but we are not sure that there aren't problems out there, so we think that adequate scientific studies need to be done to determine if there are problems.

Mr. **Molinari**. That is where I have a problem. You are not sure that there are significant health problems out there. You are completely ignoring the empirical data that exist all across this Nation. Every place where you have a known dump site of a serious magnitude, the people living in the vicinity are exhibiting similar symptoms. I am no expert, but when I hear the same symptoms—nausea, severe headaches, severe rashes, urinary infections in the case of females, and some of the others worse than that, bronchial conditions, asthma in very high quantities, what I suggest to you is that you are blinding yourself to the obvious. You have an industry bias and you simply are not looking at reality.

Dr. **Karrh**. I don't agree with you, sir.

Mr. **Molinari**. Of course, you don't agree with me. I would fall off the chair if you agreed with me.

Dr. **Karrh**. As Dr. Carnow said earlier, occupational, environmental diseases are not unique diseases. They are the same as all other diseases. People all over the country have all the diseases you are talking about. Just because they have the disease doesn't mean they are related to waste disposal sites. They mean they are people, and people have diseases. We want to find out if they are related to waste disposal sites.

Mr. **Molinari**. If you weren't a representative but a member of Congress, or an EPA, state or city health department official, and you know there is a site and that the people surrounding that site are running to their doctors in high numbers, all having the same symptoms, don't you begin to say there might be a problem that should be addressed?

Dr. **Karrh**. Absolutely, and I would turn to EPA and CDC and the chemical industry, saying you ought to do adequate studies to see if there is a relationship to that. That is precisely what we are doing, studies encouraged by lawsuits and others to get CDC to do the studies to see if there are problems related to waste sites.

Mr. **Molinari**. Has there ever been a study conducted and completed which concluded that, in fact, the health problems were caused by chemical agents near the premises?

Dr. **Karrh**. Yes. I reported that in my testimony. The Hardeman County, TN, study indicated that people were suffering some change in their liver function studies as a result of a contaminated aquifer. Once they stopped using the water from that aquifer, their symptoms went away. Studies do show whether or not there are health problems related to waste disposal sites, if you do the studies properly and adequately.

Mr. **Molinari**. Regarding those who suffered from the liver problems during that time, whatever the time frame was, do you think they should be compensated for the problems that they had?

Dr. **Karrh**. Our position is that any victim, any person who is a victim of the action of someone else, whether it is a chemical company, a person or an individual or anyone else, that has a compensable type of condition, should be compensated by the person that caused the injury.

Mr. **Molinari**. I am happy to hear that.

Dr. **Karrh**. It was in my testimony.

Mr. **Molinari**. Yes; I know. You read it.

Dr. Carnow, do you agree——

Mr. **Levitas**. Can I ask one question on that point before you go on to another?

Mr. **Molinari**. Sure.

Mr. **Levitas**. What degree of scientific evidence or proof do you think should be required as a result of these studies, in order to bring about action, either in the case of compensation provided under the existing tort system, under a system of victims compensation which Congress might legislate, or for EPA to take action such as that taken on Times Beach?

How much information do you have to have before you would, as a scientist, be willing to say now is the time to make a decision or pay compensation?

Dr. **Karrh**. That is a question that you can't answer with an across-the-board answer, because it will vary a lot from the types of data that you have and the strength of the study that you do and the so-called power of the study, and other things.

It would vary tremendously. But under the tort system, the definition of scientific certitude is quite different than it would be under some other type of compensation scheme because there the decision is made by a judge or jury based upon their evaluation of the data that is presented.

Under a compensation mechanism, if such a mechanism was put in place, you would like to have the available data reviewed by the appropriate scientific expertise, whether it is an individual or a group of individuals, to come up with an opinion that, yes, based upon the data that are available, there probably is good scientific evidence there is a cause-effect relationship. You wouldn't want to just take anecdotal information and then fashion some type of remedy from that.

Mr. **Levitas**. Does it have to be scientific certainty or reasonable likelihood?

Dr. **Karrh**. I think that would depend upon what the individual who was either adjudicating the case or the scientist who was looking at it decided. In my own opinion, if the scientific data was adequate to lead me to conclude that there most probably was a relationship, a cause-effect relationship, then that would be adequate for me. Someone else may want to see 90 percent probability. Other people are satisfied with much less, 25 or 30 percent, but generally that is not a good scientifically valid type of relationship.

Mr. **Molinari**. But you wouldn't agree that the problems in Times Beach, the health problems complained of by the people there, most probably were caused by the presence of dioxin in the vicinity?

Dr. **Karrh**. I can only answer that, Congressman, by saying as I said earlier, that based upon the data that I have reviewed, both in scientific data and in the lay press, I have not seen anything yet that convinces me that the problems they have, or anything that even makes me think that the problems they have, are related to the dioxin contamination of Times Beach.

I hope that other studies are done such as Dr. Carnow talked about and these studies will be published, and then we can do, scientific peer review and let a group of scientists, not me but groups of independent scientists, decide whether or not there is a cause-effect relationship.

Mr. **Molinari**. But you would go along with the recommendation that the people be moved from the area?

Dr. **Karrh**. No, sir. As I said earlier, based upon the data I have seen, I would not go along with that recommendation at this time, but that is a decision that was made from an administrative standpoint that I had nothing to do with, and consequently was not consulted on.

Mr. **Molinari**. Dr. Carnow, Dr. Karrh said in his testimony that CMA "has found only two valid epidemiology surveys of populations relative to waste disposal sites." Do you believe that to be accurate, from your own background?

Dr. **Carnow**. Well, it depends on what your definition is of waste disposal sites, and it depends on your definition of study. If you are talking about full-blown studies, not many full-blown studies have been done.

Mr. **Molinari**. Surveys. I guess there is a difference, I don't know. I have to ask you people, the experts. Is there a difference between surveys and studies?

Dr. **Carnow**. Again, I recounted to you at least a half dozen. I believe that there are more. There have been reports in areas in the West, where people have been exposed to radioactive tailings of increases in leukemia. There have been other reports. Again, I have not done these studies, but I am firmly convinced that if we look very carefully, we will begin to make associations. One of the problems that Dr. Karrh alluded to is the question of scientific certainty.

I think that you are not going to find the kind of pure values you want if you look at cancer and only look at a thousand people, because 10 cancers in 1,000 can be epidemic, if it is a population that doesn't have a lot of cancer, so that you may have to wait 200 years before you can make a determination.

We estimated you have to use 600 animals, and so on and so on, for various valid experiments. If you are talking about cancer, you have to use thousands in order to make a determination. Again, the problem that we have, a physician will make a diagnosis on a patient with very little evidence, because the realities of life say that you have to, and it is based on a history of physical exam and some lab tests.

When you have more than one individual, you have groups of individuals, they have similar symptoms, again if you just take the dioxin business, there is such a repetition of these kind of findings that there is no question in my mind about what these people have, based on what you have told me. Again, I have not examined them, but those whom I have examined, who have those symptoms, have exhibited physical findings and laboratory abnormalities which are consistent with and in some constitute a dioxin syndrome.

Let me just mention in regard to remaining in Times Beach. I think that, certainly in regard to animals, we know that dioxin is the most potent cancer promoter known. It is 30,000 to a half million times more potent than 3 methylchlorolanthene, which has been used to spike research so that animals will develop lots of tumors. I have read—I have not seen this study—that NIOSH, National Institute of Safety and Health, has developed a registry of dioxin workers.

It has been in effect for 2 years. I understand that they will be publishing a report which suggests that they found in the first 2 years 25 times the normal numbers of sarcomas, which is a form of cancer, in these workers. Again, I have not seen the study, but in any circumstance where you find an excess of cancer, particularly this kind of cancer, and you know that there are levels, significantly high levels in a place—and I think they were measured at Times Beach and they were high, certainly 30 to 50 to 100 times higher than CDC considered safe—it would seem to me you would have a responsibility to remove people.

Again, recognizing the dislocations, the trauma to the people and so on, I cannot feel that those people should have been left there waiting for peer value to appear.

Mr. **Molinari**. Dr. Carnow, have you ever appeared as a witness for a plaintiff in a court suit based on health injuries that were allegedly caused by exposure to hazardous wastes?

Dr. **Carnow**. Yes, I have. In regard to dioxin, in Missouri there were 47 railroad workers who were exposed, and I examined all of those workers, my staff and I examined all of those workers, on two occasions. It was our medical opinion that these workers were suffering from a syndrome, a disease complex caused by dioxin; yes, I did.

Mr. **Molinari**. In deference to the other members of the subcommittee, I am going to ask one more question until it is again my turn. I would just like to ask you, Dr. Karrh, would you have any apprehension about moving your family into Times Beach and living there for, say, from 1 to 5 years? How would you feel about the possibility of a health problem affecting you there?

Dr. **Karrh**. Based upon the information I have seen, I always have to preface it in this way because I have not been to Times Beach, I would have no hesitation moving my family to Times Beach for 4 or 5 years.

I would like to point out on the incident that Dr. Carnow just mentioned, the Sturgeon, MO, incident where the 47 people were supposedly injured by a transportation accident, that precisely supports the position that the chemical industry has taken in that we are saying that we don't know if there is a problem or not.

If there is a problem, we don't yet know the magnitude. We want to do studies to find out exactly what that problem is, and the magnitude. But in the meantime, the existing systems, existing mechanisms, are adequate to cover the victims compensation issues until we find out what the magnitude of the problem is.

The 47 people in the Sturgeon, MO, situation, through the court system, received a settlement of $58 million, if you can believe in the American Lawyer Journal report, and that seems to have been compensation for any injuries that they may have suffered. That is in Sturgeon, MO.

Mr. **Molinari**. I have to ask you one more question, since you said that you would have no hesitation, based on what we know, to move your family into Times Beach, MO. Pardon me for being blunt, but if you did that, and your family started to experience symptoms like nosebleeds and rashes and kidney problems and nausea, sore throats, bronchial conditions—symptoms that everybody else is getting—how long would it take you to get the hell out of that area?

Dr. **Karrh**. I think that is a question, Congressman, that everyone would answer differently. I certainly would evaluate the data that I had, and I would look at it scientifically and objectively and decide whether or not it was related to the place where we were living or if it was something else. I wouldn't arbitrarily, because I was emotional about it, jump to the conclusion that it had to be the place we were living.

Mr. **Molinari**. I may disagree with you but I admire you for your consistency.

Dr. **Karrh**. I was sworn in when I became a witness, and I have tried to stay honest.

Mr. **Levitas**. Thank you, Mr. Molinari. We will go back around. I have a couple of other questions.

As I look at the nameplates out there, everybody has the name preceded by Doctor. We have our own doctor on this panel as well, and I now recognize the gentleman from Georgia, Dr. Rowland.

Mr. **Rowland**. Thank you very much, Mr. Chairman, and may I take this opportunity to welcome you, my colleagues, to this committee hearing, and tell you how much I appreciate your being here. We are confused, it seems, whether or not certain of these processes are caused by these agents. The Congress is somewhat confused by the contradictory testimony in the hearing.

This is certainly the problem we are trying to resolve at this time. For example, yesterday we heard from the mayor of Times Beach, we heard from her about many, many different disease processes that she related to exposure to dioxin. On the other hand, I have heard in the Veterans' Affairs Committee that there were veterans who were in Vietnam that were drenched with dioxon day after day, month after month, several years ago, and experienced apparently no ill effect from this having taken place. So you can see the contradictions that we are hearing.

The mayor yesterday testified, some staggering testimony to me, that in Times Beach there were teenagers who were experiencing breast cancer, which she related to the exposure to dioxin. I have been in medical practice for 30 years and I don't recall ever seeing a teenager with breast cancer.

She told of a family that had a child with neuroblastoma. Very unusual chances. The chances of that happening, again, were extremely rare, the next child she had was also born with this. She talked about one block with 15 families and several of those households had seizure disorders.

We heard this over and over, pelvic tumors, for which there was no diagnosis, and I inquired about pathologic reports. No pathologic reports. The doctor just said they didn't know what the cause was.

It is very confusing, the testimony that we have been hearing, and I realize that it is very difficult to have absolute determination of whether or not these chemicals are causing these disease processes, and it takes a long time to determine that.

I would like to ask about the Times Beach testimony that we heard yesterday. Do we have, to your knowledge, any documented evidence from physicians of some of those things that I mentioned that she testified about yesterday, to your knowledge?

Dr. **Karrh**. I have no knowledge, documented knowledge, documented information from physicians regarding what you describe as being testified to yesterday.

Mr. **Rowland**. Dr. Carnow?

Dr. **Carnow**. No. Again we don't solicit, as you know, physicians. I have not been called into Times Beach by anyone, so I have not been privy to the medical records. I have spoken with the mayor on a number of occasions. And I do know about some of the problems that she has expressed. I have not seen physicians' records.

I also know that the things that you recount, what we have seen in other communities and that others have reported in other countries in other circumstances, and so on, there is a commonality of symptoms and findings in regard to this chemical. I think sometimes, however, that, you know, this chemical is such a very toxic one that I think it is actually relatively easy to make associations. I think the problems we have are with those chemicals not quite as deadly, not quite as toxic, in trying to make determinations about relationships.

I have no difficulty in my mind with the relationship with dioxin given a good test protocol which includes neurophysiologic, central nervous system, liver, a host of other tests which look at many parameters that dioxin can affect. Again, what you are talking about is something that I am familiar with, not in Times Beach, but in other groups we have examined.

Dr. JASON. Dr. Henry Falk at CDC has been heading up a program to look at the chemical analysis of the individuals involved in Times Beach. They have a group of around 140 individuals thus far where they have looked even at immune function. I think he would probably help you out with some of your questions concerning their look at cancer incidence, also. So I think probably the most appropriate people in this case would be the CDC and Dr. Falk who has been looking into that area.

Mr. ROWLAND. Do you know if they have established a relationship?

Dr. JASON. Some of the analyses even of the blood at this point is just being done. So I think it would be premature to draw any real conclusions. He can tell you the status of the chemical analyses. I am not aware of how intensively they have looked at the cancer incidence. One of the jobs I have at EPA is risk assessment. Present data sets, whether they be the National Cancer Atlas or others, are usually a mortality indices. What we are dealing with here is a changing spectrum in the use of health outcome data.

If we look at the childhood cancers, these children are actually surviving. The majority of these children are not dying. So if you look at mortality statistics to address areas of concern, it can be misleading depending on age groups you are looking at. So the kinds of data sets we have relative to the areas of concern could be misleading in some cases depending upon the age group examined. It is a concern of our agency to go further in this area.

Mr. ROWLAND. Would you say at this time, then, that the disease process as it has been reported from Times Beach has not been established as a cause-effect relationship with dioxin?

Dr. JASON. I think the difficulty, speaking not only as a physician but a scientist, also, is the fact that isolated reports are very difficult to handle, mostly because of the fact that diseases do occur, even occasionally constellation of diseases occur but with rarity. As you begin to accumulate more and more data as Dr. Carnow was saying, it becomes less and less likely. I think one of these that would be helpful would be medical records, an occasion to look at those individuals and make sure that what we are seeing is consistent with what is being reported.

I think that is always the difficulty. The human tragedy of illness is something that is certainly in all of our minds. It gets down to the bare essentials of what is the disease process? Is there consistency of the specimens with a common etiology. I would say in answer to your question yesterday about whether a pathological diagnosis made, some diagnosis was made. Something may have been written that said it was impossible to make an absolute diagnosis, but there will be at least a histopathological description of the cells. So I think there is information one can still draw upon. At least that is generally the case in medicine. I would hope that Times Beach uses a similar medical procedure.

Mr. **Rowland**. I guess that we are impatient to learn about this. Mr. Molinari referred to that on more than one occasion. Do you have any idea of when we might learn of the relationship insofar as Times Beach?

Dr. **Jason**. I think the difficulty to a certain extent, perhaps because I am a pediatrician, is the fact that if we look at the turnaround time in events such as cancer, we talk about latency periods in many cases of 14 to 30 years. The mobility of a young population is such that even if cancer were to occur and that is the chosen outcome, many of the individuals will have already moved. So it will be difficult to look at an increase in a specific area, and trace it back to the appropriate exposure. If we look at others, such as Dr. Carnow's suggestion of major malformations, as one, it is extremely important to address that issue. As I am sure some of you may know, the birth defects monitoring program of CDC has been attempting to do that over 12 years.

There are many inadequacies of the BDMP data base which they realize. It was an organized attempt however, to look for areas of increase in birth defects. Thus far they have not been able to find a single chemical or drug related birth defect outcome using the birth defects monitoring program. This raises some concern over the sensitivity of this type of approach for our needs.

We at the Agency right now are using another one. That is the birth weight, which is an extremely sensitive indicator, perhaps overly so. But it is consistent with the animal evidence of embryo toxicity. In this case, in conjunction with New York, as a matter of fact, Mr. Molinari's area, we are working with the census tract level to look for statistical increases of low birth rate that may be correlated appropriately with exposure.

The reason I think that this is important is that it is very difficult with long latencies, even in chronic diseases to begin to associate or even correlate a given exposure with a given outcome. I think we have to be thinking in the direction of several indices that have been formulated. One is the National Death Index where given a person's name, if we have a list of individuals in a certain area, we can find out if they have died. And if so, what the cause of death was through the death certificate.

Thus we begin to refine our approach of finding mortality data compatible with the exposure. We have the Chronic Disease Index which is presently being developed through CDC. As you can imagine the problem there will be inadequate ascertainment for certain areas as well as an inappropriate diagnosis in certain cases. The same problems that plague major malformations reporting will be a problem here, not to say it isn't important, but that we have to realize the limitations of the data we are using. When we talk about body burden on an individual basis, as Dr. Carnow has already said, it is very difficult in many cases to get accurate data.

For example, to get enough adipose tissue to do a dioxin analysis would be on the order of a one-half gram of adipose. We would have to go in with a scalpel to be able to get enough tissue. So an adequate source of reasonable substance, whether it be blood, adipose tissue, or whatever, to begin to draw the important kinds of correlations can some times be very difficult. Not impossible, but certainly difficult.

Mr. ROWLAND. In that respect, the long turnaround time, Mr. Chairman, there are a few more questions I want to ask.

Mr. LEVITAS. Go right ahead.

Mr. ROWLAND. Dr. Lewtas, I may refer to this, would chromosomal analysis help us any and shorten that turnaround time with reference to dioxin?

Dr. LEWTAS. I think there are beginning to be in addition to chromosomal analysis, a number of genetic human monitoring tools available which we can use in population studies. CDC is using these tools, and did use them in Love Canal. I am not sure whether they are being used in Times Beach or will be used there. I think those tools are useful in that many of those methods are rapid and that should help. In addition to the chromosomal analysis method, several other methods are now available for screening long term chronic effects, e.g. genetic effects, by doing analysis on blood and possibly sperm and tissues in different body fluids——

Mr. ROWLAND. Not to interrupt you but would you give me a detailed description of those techniques for the record?

Dr. LEWTAS. Yes.

Library of Congress Catalog Card Number 81-83151

The March of Dimes Birth Defects Foundation is dedicated to the goal of preventing birth defects and ameliorating their consequences for patients, families, and society.
As part of our efforts to achieve these goals, we sponsor, or participate in, a variety of scientific meetings where all questions relating to birth defects are freely discussed. Through our professional education program we speed the dissemination of information by publishing the proceedings of these and other meetings. From time to time, we also reprint pertinent journal articles to help achieve our goal. Now and then, in the course of these articles or discussions, individual viewpoints may be expressed which go beyond the purely scientific and into controversial matters. It should be noted, therefore, that personal viewpoints about such matters will not be censored but this does not constitute an endorsement of them by the March of Dimes Birth Defects Foundation.

DEDICATION

To the residents, past and present,
of the Love Canal of New York State:
Lest you think it was all in vain.

PREFACE

In 1980, the results of a cytogenetic study of the residents of the Love Canal in upstate New York created extensive debate within the scientific community and profound anxiety within the studied population. In response to the scientific controversy and out of concern for the well-being of the residents of other communities contaminated by toxic wastes, four agencies of the U.S. Government (the Center for Disease Control, the Environmental Protection Agency, the National Institute of Environmental Health Sciences of the National Institutes of Health, and the Occupational Safety and Health Administration) and a private, non-profit foundation (the March of Dimes Birth Defects Foundation) jointly organized and sponsored the Conference on which this book is based. The Conference was held from January 26-27, 1981, at the Washington Hilton Hotel, Washington, D.C., and was attended by 90 invitees.

It was decided early in the planning stages of the Conference that the emphasis would be on genetically related end points, since those were clearly and properly primary concerns during the Love Canal episode. To that end, three Panels were established: one on the cytogenetic effects of genotoxic chemicals on human populations (Panel I); one on reproductive effects (Panel II); and one on testing for mutagens in human populations (Panel III). Draft reports were prepared by each Panel of scientists, and the reports were circulated prior to the Conference. The Conference itself was devoted to a general discussion of each report, followed by an in-depth critique and revision of the report by those attendees most knowledgeable in the area. Final responsibility for the content rested with the Co-Chairpersons for each Panel: Anthony Carrano and myself for Panel I, Zena Stein and Dorothy Warburton for Panel II, and Fred deSerres and Michael Waters for Panel III. James Neel presented a summary of these proceedings from a human population geneticist's viewpoint, and Robert Miller summarized numerous other toxic exposures of humans. Their papers are an integral part of this volume.

We wish to emphasize here that the reports are meant to serve merely as guidelines to the proper conduct of the types of studies discussed. The reports represent, generally, a consensus of views on the part of the panelists, as well as of the Conference participants; but they clearly do not mean to imply universal acceptance by the scientific community of the approaches described. Our intention was simply to provide guidance to those contemplating these types of studies in human populations. The recommendations may be regarded as reasonable, state-of-the-art suggestions as of 1981.

The Steering Committee for the Conference consisted of: Fred deSerres of NIEHS, Clark Heath of CDC, James Neel of the University of Michigan, Gabriel Stickle of the March of Dimes, Dorothy Warburton of Columbia University, Michael Waters of the EPA, and myself, also from Columbia. The March of Dimes served as the coordinating agency, and in large measure, the success of the Conference was due to the efforts of Gabriel Stickle, Phyllis Wright, and, especially, Natalie Paul of the March of Dimes. Mrs. Paul did a superb job as Associate Editor of this volume, and we are very grateful to her. Marci Allmond of my office ably assisted the March of Dimes, and especially me, throughout the Conference and the preparation of the book. To all of these people, and to numerous others, I am indebted.

A high degree of interaction among agencies of the U.S. Government and among scientists of diverse orientations is reflected in this publication. This book is our attempt as physicians and scientists concerned with the public health to avoid more Love Canals.

Welcoming Remarks

Gabriel Stickle,
Sr. Vice President for Planning and Administration
March of Dimes Birth Defects Foundation

On behalf of the March of Dimes Birth Defects Foundation, one of the four sponsoring organizations, I welcome you to the Conference on the Evaluation of Human Populations Exposed to Potential Mutagenic and Reproductive Hazards.

It seems unnecessary for me to elaborate on the motives for organizing this conference. For many months in 1980, Love Canal shared the front pages with Iran, and our direct attempts at their solution had failed in both, or so it seemed at the time. The bitter aftertaste of our failure was tinged with the fear that we may fail again, if the scenario were to be repeated. If ever the time were ripe to formulate guidelines to study actual or suspected environmental hazards to a localized population, it is now.

We are not under the illusion that guidelines, by themselves, will solve the problem, that is, will achieve a consensus as to the presence, magnitude, and nature of the hazard or who in fact is at risk and to what degree. The interactions among ecologic, medical and sociopolitical factors involved in a situation like Love Canal are so complex and so little understood that we must know much more than we do now to be confident about what public health measures are needed to protect people from potential hazards of the high technology society.

What the guidelines could do, of course, is to minimize mistakes. This is the first and necessary step in achieving adequate control. Equally important is that the guidelines may help close the ranks of the scientific community faced with other Love Canals. Divided opinion among experts generated a kind of intellectual smog that still hovers over Love Canal. And not a little of the anxiety and heartache of Love Canal residents must have come from uncertainty about purported dangers which fanned the flames of uninformed speculation.

It goes without saying that whatever guidelines emerge from this meeting will be subject to continuous revision and amendment as we gain in experience and understanding. A standing interagency committee to carry on this task may be in order.

While science has much to do, the public has much to think about. Faced with a potential danger, many of us conjure up an apocalypse. Nuclear energy has conditioned us to this propensity, perhaps to a degree that may not be appropriate to most other environmental hazards. The public and its principal information source — the media — have to learn to balance the fear of missing hidden hazards against the harm of inflating non-hazards.

The public needs to learn that there is great variation not only in the way a mutagen or teratogen reaches human subjects but also in human capacity to detoxify these agents. Of 10 pregnant women exposed to a teratogen one may have a spontaneous abortion, another a growth-retarded baby, another a child mildly mentally retarded at age 3, and the rest may have normal offspring. The timing and intensity of exposure may have contributed to the outcome but so could the ways in which the 10 mother-fetus pairs disposed of the teratogen.

In these and other respects, therefore, there is a need for better public understanding that clearly matches the need for better professional judgment. The intention of the March of Dimes is to serve both these needs.

With that I shall wish you well in your labors and give the podium to the organizer of this conference, Dr. Arthur Bloom.

PREFACE

When cells are exposed to either physical or chemical mutagenic carcinogens, one thing that is readily seen is induced cytogenetic damage. If the damage is in germ cells, in theory it can lead to sterility in the exposed individuals themselves or to detrimental mutations that could be expressed in their offspring or descendants. If the damage is in somatic cells, it possibly could lead to somatic effects such as cancer or even premature aging. This somatic damage usually is manifested as increased levels of chromosome aberrations or sister chromatid exchanges (SCEs), which can be quantitatively related to the exposure.

With ionizing radiation, which is the most extensively studied mutagenic carcinogen, the induction of aberrations in long-lived circulating lymphocytes has proved its utility as a biologic dosimeter to estimate the absorbed dose.

With chemical mutagens the situation is more complex. For instance, the mechanisms of interaction with DNA differ, and such factors as the presence or absence of activating or deactivating enzymes, the biologic and chemical half-lives of the chemicals, the degree of DNA repair, etc., all can affect the yield of aberrations. Nevertheless, the formation of chemically induced cytogenetic changes in lymphocytes of exposed people has already shown itself to be a sensitive indicator of low level exposures, brought about by such factors as occupational exposure (e.g., uranium workers). The cytogenetic system, then, is among the most sensitive systems that can be used to monitor exposure of human populations.

It should be noted that, while chromosome aberrations are deemed undesirable, as are induced mutations in general, the presence of cytogenetic changes cannot be used to predict specific health effects in an individual. However, they do give an estimate of the magnitude of an exposure that could increase the risk of disease in the population.

Consequently, cytogenetic study of both chromosomal aberrations and SCEs has a clear place in the evaluation of human populations exposed to known or suspected mutagens. However, such studies must be done carefully, with appropriate controls and with proper methods for statistical analysis of the data. This document attempts to provide a consensus by cytogeneticists of how such investigations should be structured, what laboratory techniques should be used, and how the resulting data may be reasonably interpreted.

I. CYTOGENETIC INVESTIGATIONS: BACKGROUND

Determination of chromosomal aberration frequencies in peripheral blood lymphocytes from persons or populations exposed to ionizing radiation has become an established technique, and substantial agreement among cytogeneticists has been achieved as to methodology and confounding variables [1]. Unfortunately, the current state of our knowledge of the cytogenetic end points of interest in connection with other, particularly chemical, mutagens has not always been available to those sponsoring, planning, or evaluating such human cytogenetic investigations. This document attempts to provide those so involved with a consensus view by cytogeneticists of the current state of our knowledge of the technical and procedural factors that properly should be considered in such investigations.

While there is ample evidence of the usefulness of cytogenetic measurements to detect ionizing radiation exposures of human populations, (such as the survivors of the atomic bombings of Hiroshima and Nagasaki [2], uranium miners [3], nuclear dockyard workers [4], and others), experience with cytogenetic studies of populations exposed occupationally or environmentally to chemical agents is still very limited. Hence, studies of populations so exposed must be approached with caution. Our lack of knowledge about normal background levels of aberrations, about sources of variation and important confounding variables, and the sensitivity of different cytogenetic end points for detection of exposures to low levels of most chemical agents presently precludes a detailed description of just how a "proper" study should be designed, except in the broadest terms. Though it is doubtlessly going to be deemed desirable to do some studies of individuals or populations whose exposures are ill defined, a high priority must be given to those studies that can provide some of the information involving populations we now lack, such as those occupationally exposed to known mutagenic or carcinogenic agents, for whom at least some sort of dosimetry is possible.

End Points

Two end points, chromosomal aberrations and sister chromatid exchanges (SCEs), are now in wide use. Though the use of other tissues, such as bone marrow, is technically feasible, for practical purposes the only material likely to be used for population studies is the peripheral blood lymphocyte in short-term tissue culture.

Chromosomal aberrations constitute one class of mutational event, and thus their induction, even in somatic cells like circulating lymphocytes, clearly implies that there may be a germ line genetic hazard as well (providing, of course, that the inducing agent also reaches the gonads). Furthermore, many, if not most, agents causing aberrations, or clastogens, are also carcinogens, at least in animals. Determination of aberration frequencies has become a widely used and accepted radiation dosimetry technique. Spontaneous levels and confounding variables for the chromosome-type aberrations induced by ionizing radiation in peripheral lymphocytes are well established, and it has thus become relatively easy to design studies to detect particular levels of radiation exposure.

Unfortunately, attempts to use aberration frequency determination as a measure of exposure to potential chemical clastogens, especially those that induce chromatid-rather than chromosome-type aberrations, have begun only recently. Further, much of the information one would like to have to design and interpret either individual or population measurements is inadequate or unavailable. We particularly need information on spontaneous aberration frequencies, on interindividual variation, and on the persistence of chromatid aberrations and their derivatives. Until the necessary information is acquired, studies of persons or populations exposed to chromatid aberration producing agents, and the interpretation of chromatid aberration data must be approached conservatively.

SCEs, in contrast to aberrations, are not, as far as we know, mutational events, in the strict sense. We are aware of no health consequences of SCEs *per se*. Determination of SCE frequencies is, nevertheless, widely advocated as an indicator of potential genetic or carcinogenic hazard. Many believe the phenomenon to be a manifestation of some form of repair of damaged DNA or an indicator of mutation. A large number of mutagens and clastogens have been shown to induce SCEs and, for a number of agents, increases in SCE frequencies are associated with increases in gene mutation and are detectable at levels of exposure far below those required to produce detectable increases in chromosomal aberration frequencies. In addition, many persons find SCEs quicker and easier to score than aberrations. To the extent that SCEs are a measure of DNA damage which is likely to result in mutagenesis and carcinogenesis, it seems reasonable to include SCE frequency as an end point in cytogenetic studies, It is important, however, to note that there is a major class of mutagens and carcinogens (ionizing radiation and a few truly radiometric drugs) that are poor inducers of SCE, just as there are others (like diethylstilbestrol) that are poor inducers of aberrations.

Though there is controversy as to whether truly spontaneous SCEs exist, or whether all of those seen in otherwise untreated cells are in fact the result of the incorporation of the base analogs required for their expression, for practical purposes there is a background level of SCEs against which any increases in frequency must be measured. The levels seen are numerically far higher than spontaneous chromosomal aberration frequencies, with a number of SCEs generally being present in each metaphase spread examined. Furthermore, the study of variation in human peripheral lymphocyte SCE frequency and the factors influencing it has begun only recently. Thus, as with chromatid-type aberrations, we still lack much of the information necessary to design and interpret SCE studies as confidently as we would like.

Populations

Cytogenetic studies of persons or populations for increases in chromosomal aberration levels have been useful in two ways. As already suggested, aberration frequency determination has become a standard method of biologic dosimetry in cases of individual known or suspected exposure to ionizing radiation. It has proven particularly useful in cases where possible exposure has been suggested by physical circumstances, even though actual exposure seems unlikely. If no increase in aberration frequency is found in such a case, the cytogenetic findings suggest that no significant exposure did in fact occur, often providing significant relief of anxiety. It must be kept in mind, of course, that a negative finding does not rule out *some* exposure, any more than finding an aberration indicates definitively that there *was* some exposure. Though we now lack much of the background information necessary to derive a cytogenetic "biologic dosimeter" for chemical mutagens and carcinogens, it seems likely that we will ultimately be able to use aberration (and SCE) frequencies in a quantitative fashion in chemically exposed populations.

The second useful application of cytogenetic studies has been the study of populations exposed to ionizing radiation, both at low and high exposure doses. In this application it has proven possible to demonstrate statistically significant elevations in aberration frequencies for populations, and even subpopulations, grouped by broad dose categories, even though individual levels may not be elevated significantly above suitable controls. The extension of such studies to populations occupationally or environmentally exposed to other potential mutagens and carcinogens must be approached with caution, however. It remains to be confirmed that chromosomal aberration measurements are sufficiently sensitive to "detect" occupational (i.e., mostly low) levels of exposure. This confirmation will be dependent on the availability of physical dose estimates, and would, of course, be impossible for exposures to indeterminate doses. Needless to say, such confirmation studies must include carefully selected control groups, and attention must be given to the existence of both *known* (for example, other drug or radiation exposures) and *unknown* confounding variables.

Another possible application of cytogenetic studies of populations is for qualitative "triage," to sort out the more heavily exposed members of a population of individuals exposed to differing doses. This might be of use in tracking down the identity and source of some clastogenic or SCE-inducing agent, for example, or even as a basis for clinical management, in the case of uneven, accidental exposures of human populations.

II. METHODS FOR THE STUDY OF INDUCED CHROMOSOMAL ABERRATIONS

It is recognized that a wide array of protocols exist for the culture of human peripheral leukocytes for the purpose of doing cytogenetic analysis. It is not the intent of this Committee to recommend specific protocols to be followed in cytogenetic studies but rather to discuss the general problem areas that, if not considered, can invalidate a cytogenetic monitoring study. The problem areas that are the most easily identified are: 1) the assurance that the maximum effect is observed; 2) the introduction of extraneous factors that can modify the observed effect; 3) the identification of the appropriate cytogenetic end points to be screened for and the application of the best procedures for detecting them; 4) the randomization of both control and study cultures and the blind analysis of the slides; and 5) the possibility of not observing a clastogenic effect due to the inherent insensitivity of the human peripheral lymphocyte system to in vivo exposures of certain classes of chemicals.

Past experience with ionizing radiation has amply demonstrated, and reemphasized, the necessity of analyzing cells in their first posttreatment mitotic division in order to determine the maximum frequency of chromosomal aberrations. This is particularly true for exposures to purported chemical mutagens. It has been established that the great majority of chemical clastogens are S-dependent [5]. S-dependency, in the case of cytogenetic phenomena, means that the substance must either be present during replicative DNA synthesis, or the lesions it produces in the chromatin require replicative DNA synthesis to be translated into a structural aberration. The aberrations so produced are invariably chromatid-type and very transitory in that they are generally lost at the next cell division. This loss is either through cell lethal effects or through conversion to chromosome-type aberrations. Although, most chromatid aberrations are cell lethal, a significant frequency are expected to persist as balanced symmetric aberrations (e.g., reciprocal translocations and inversions). These aberrations are difficult to score with as high a degree of quantitative precision. Hence, the analysis of 2nd, or later, divisions will greatly underestimate the true level of damage produced by S-dependent clastogens, particularly if the effect is being produced by a long-lived lesion that was induced in vivo.

A method of insuring the analysis of 1st division cells that has been widely used in radiation studies is that of adding BrdUrd to the culture medium and performing one of the differential staining procedures that allows for the detection of 1st, 2nd, and subsequent divisions. The investigator can insure the observance of the maximum effect by analyzing only 1st division cells. If this procedure is employed, the investigator is urged to employ a BrdUrd concentration that does not significantly elevate the spontaneous aberration frequency. If the BrdUrd procedures are not utilized, care must be taken to insure a maximum frequency of 1st division cells. This can be done by fixing the cultures at an appropriately early time, usually 42-48 hours after initiation, depending upon the culture medium. It is noted, however, that fixation after 54 hours is unacceptable. By definition, S-dependent chemical clastogens are not expected to produce structural aberrations directly in the circulating lymphocytes as less than 0.1% of the lymphocytes possess an S phase. They may produce aberrations during the in vitro S phase if the lesions persist, as discussed, but they will generally produce their effect in the lymphocyte precursor cells. Therefore, the most common type of aberration that is expected to be observed is the chromosome-type lesion that is derived from an initial chromatid-type lesion. The majority of these are expected to be of the balanced symmetric type, and unless highly unequal so that obvious karyologic changes occur, will be difficult to quantitate. It has become a common practice in some laboratories to score banded chromosome preparations. It is felt that the use of banded chromosomes does not sufficiently increase the sensitivity of detecting the balanced aberrations. This, coupled with the difficulty of scoring chromatid-type aberrations in banded preparations, removes the necessity of scoring banded preparations, in the view of this Committee.

On the other hand, in those instances in which F_1 studies are conducted and only the balanced symmetric aberration types are expected to be seen, the slight-to-moderate increase in the efficiency of detecting them in banded preparations justifies the use of banding procedures.

There are many tissue culture media and medium compositions that are suitable for the culture of human peripheral blood lymphocytes. The precise medium composition is left up to the investigator. However, the use of virus-free serum is mandatory and care should be taken to avoid the addition of any other substances that conceivably could produce chromosome aberrations. Although the use of whole blood presents the possibility of carry-over of a mutagenic substance from the donor's serum, thus leading to the in vitro production of aberrations, this procedure is acceptable. Regardless of the culture method employed, it is advisable that duplicate cultures be established from each blood sample and that an equal number of cells be scored from each culture.

It is recognized that situations will arise in which it will be virtually impossible to initiate cultures immediately after blood sampling. In those instances, the blood samples should be stored at 4 °C and cultures should be initiated as soon as is practically possible. Storage time in excess of 5-7 days will probably result in poor growth.

In any study of this type, extreme caution must be taken to eliminate possible observer bias and subjectivity in the analysis of the slides. Perhaps the best method of preventing this situation is to randomize and code control and study group blood samples, and culture both simultaneously. In addition, it is also advisable to treat several cultures with a known clastogen to serve as a positive control. A further step that should be taken is to randomize, and code, all of the slides.

Because most chemicals are S-dependent and, therefore, are expected to be inefficient at producing structural aberrations in the circulating lymphocytes, the cytogenetic analysis of circulating lymphocytes is anticipated to underestimate greatly, if it even detects, the true effect a clastogenic agent will have on normally proliferating cell systems. Hence it can be anticipated that a small effect observed in the lymphocytes of exposed individuals may represent a minimum frequency estimate in relation to the effect that may occur in bone marrow, or spermatogonial cells. In order to avoid a gross underestimation of the potential true hazard posed by S-dependent chemicals, whose mode of action is not known, it seems advisable in those instances when exposure to only one or two known substances occurs, to perform an in vitro experiment to define the effect, and perhaps the mechanism of action, of the substance in pure culture. This experiment can be done prior to, or concurrent with, the population study. It should be carried out in a fashion that will, however, provide maximal information on mode of action and dose-response characteristics. Such experimental procedures are outlined in the EPA GENE-TOX Guidelines.

Finally, the possibility of chemically-induced mitotic delay in a sensitive subpopulation of cells might reasonably be considered in the design of a study. A precaution that can be taken to guard against this eventuality is to perform fixation at two or more time intervals. Of course this may increase significantly the work involved, but mitotic delay is of the same concern in vivo, as it is in vitro.

III. ANALYSIS AND CLASSIFICATION OF CHROMOSOMAL STRUCTURAL CHANGES

In the literature there are numerous classifications of structural chromosomal aberrations. We do not suggest that the classification system presented here is the only possible one, nor that it is necessarily the one that should be adopted. This system is a composite of those published earlier by Evans [6] and Savage [7], and is one which the panel members readily agreed was clear and accurate.

Induced chromosomal aberrations are divisible into two main classes: chromosome-type and chromatid-type. In general, chromosome-type aberrations involve both chromatids of a chromosome, and chromatid-type involve only one of the two chromatids (one exception is the isochromatid deletion which is discussed later). Also, in general, chromosome-type aberrations are induced in the G_1 stage of the cell cycle (i.e., prior to replication) while chromatid-type aberrations are produced during the S or G_2 stages (i.e., during or after replication). A few agents can induce aberrations in all stages of the cell cycle: chromosome-type in G_1 and chromatid-type in S and G_2. Examples of these chemical and physical agents are x rays, bleomycin, cytosine arabinoside, streptonigrin and 8-ethoxycaffeine. The vast majority of agents almost exclusively induce chromatid-type aberrations, even in cells treated in G_1. The fact that chromatid-type aberrations are induced from treatment of G_1 cells suggests that much of the DNA damage is not repaired before DNA replication, and that, as a result of replication of damaged DNA, chromatid-type aberrations are formed. This implies that the majority of agents to which humans might be environmentally or occupationally exposed will induce chromatid-type aberrations — an important point to be discussed again below.

Peripheral lymphocytes are noncycling cells and are in G_1, or to distinguish them from cycling cells, in G_0. Damage from most agents to the DNA of these cells will be repaired, albeit slowly, in G_0, or during the rather long G_1 of the 1st cell cycle, once the cells are stimulated to enter the cell cycle by a mitogen such as phytohemagglutinin. This low rate of repair makes the probability of producing an aberration low. (The repair of DNA damage by agents capable of producing aberrations in G_0 or G_1 appears to be more rapid.) The relatively long time interval between exposure in G_0 to the S phase in tissue culture means that a large proportion of the DNA damage will be repaired before the cell reaches the S phase. Thus the probability of chromatid-type aberrations being induced as the result of replication of damaged DNA is reduced. Since population exposure levels are likely to be low, there will be only a small probability of our observing chromosomal aberrations from the exposure of G_0 peripheral lymphocytes.

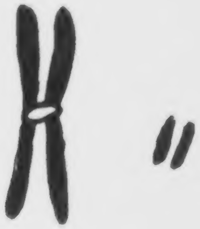
Those few agents that can induce aberrations in all stages of the cell cycle can induce aberrations in G_0 peripheral lymphocytes, and these will be observed as chromosome-type aberrations at mitosis. Since a significant proportion of human lymphocytes are long-lived, the cytogenetic effects of a dose accumulated from chronic exposures may be measureable.

The aberrations more likely to be observed will be those induced in lymphocyte precursor cells, which are cycling cells. Again, the aberrations induced by the majority of chemicals will be of the chromatid-type, but will not be observed as such at the first in culture mitosis. They will be seen as derived chromosome-type aberrations. This is due to the fact that there will be one or more cell divisions between induction of an aberration in a precursor cell and its observation in stimulated peripheral lymphocytes. Chromatid-type aberrations are essentially converted into chromosome-type aberrations as a consequence of cell division. The types of derived aberrations will be discussed later. As a result of cell killing caused by the loss of acentric fragments in mitosis, and of the mechanical interference with cell division caused by exchange aberrations, there is a significant probability that induced aberrations will be lost before the cell population is analyzed. This loss of aberrant cells will decrease the sensitivity of the assay, since the observed frequency will be less than the induced frequency. At low exposures, and consequently low aberration frequencies, this is of particular importance. Similar factors will influence the observed aberration yield from exposure to agents that induce appreciable aberration frequencies in all stages of the cell cycle. In the precursor cell, the chromatid-type aberrations induced in S and G_2 will either be lost at subsequent mitoses or will give rise to derived chromosome-type aberrations. The majority of chromosome-type aberrations (with the exception of reciprocal translocations and inversions) will be lost from the analyzable cell population, since the loss of acentric fragments or the mechanical interference with division by rings and dicentrics will often result, again, in cell lethality. Thus, for these potent clastogens also, the contribution to the total aberrations observed at the 1st mitotic division in culture, from induction of aberrations in precursor cells, will be small.

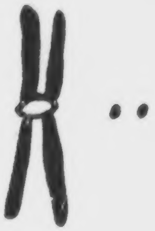
The following is a classification of the induced aberration types and the derived types observed at metaphase.

A. Chromosome-type Aberrations

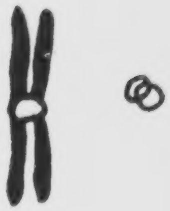
1. Terminal deletion



2. Interstitial deletions



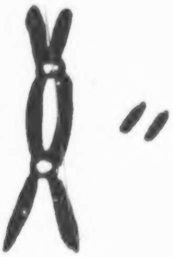
Minute



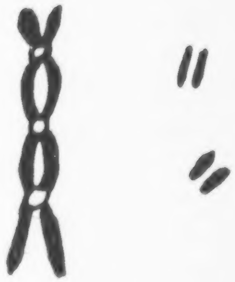
Acentric ring

The small interstitial deletions appearing as paired dots are classified as "minutes." The larger interstitial deletions in which there is a clear space in the center of the ring are classified as acentric rings. The distribution is not particularly clear-cut, and in general is merely an indication of the different sizes of interstitial deletions. The significance is not clear.

3. Asymmetric interchanges (usually dicentrics)



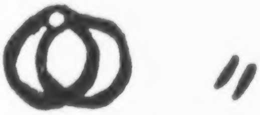
Dicentric



Tricentric

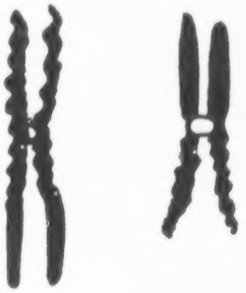
It is customary to assume that each dicentric, analyzed at the 1st mitosis after treatment, is accompanied by one acentric fragment. Thus, a cell containing one dicentric and two acentric fragments would be classified as one dicentric plus its accompanying fragment and one terminal deletion. Similarly, a tricentric is assumed to have two accompanying acentric fragments.

4. Asymmetric intrachange (ring)



As above, a ring is assumed to be accompanied by one acentric fragment.

5. Symmetric interchange (reciprocal translocation)



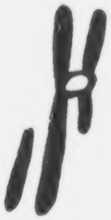
It is particularly difficult to observe this type of aberration, since the exchange often results in chromosomes that are only slightly different from the normal karyotype. It is possible to band the chromosomes, but even then the efficiency of scoring symmetric interchanges is not greatly improved. It is recommended that obvious symmetric interchanges be recorded with the proviso that their frequency is far from accurate.

B. Chromatid-type Aberrations

1. Achromatic lesions ("gaps")

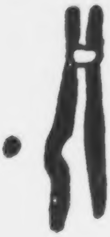
This chromosomal abnormality has been the subject of much discussion, and also confusion regarding its significance and classification. When chromosomes are analyzed at the 1st mitosis after treatment, nonstaining or very lightly stained regions are observed. These achromatic regions or "gaps" can be either in one chromatid or at identical positions on both sister chromatids. It is generally agreed that they should be recorded, but in a separate category from deletions, and should not be included in measures of aberrations per cell since their significance is unclear. It is often difficult to distinguish between achromatic lesions and true deletions. Two criteria are usually employed. First, if there is a distinct displacement of the chromatid fragment(s) distal to the lesion, the abnormality is classified as a deletion. Second, if there is no displacement, but the nonstaining region is wider than the width of a chromatid, again the abnormality is scored as a deletion. This latter definition is more difficult to interpret, and is clearly only a working definition.

2. Chromatid terminal deletions

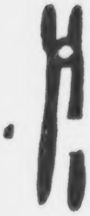


As discussed above, a displacement of the chromatid fragment, or a nonstaining region with a width greater than that of a chromatid, constitutes a chromatid terminal deletion.

3. Interstitial deletion (minute)

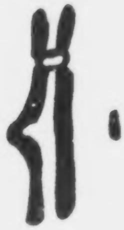


or



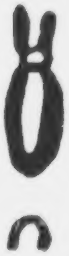
(minute + deletion)

or



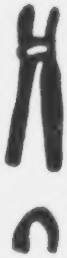
It should be noted that the deleted fragment often can be separated from the deleted chromosome, and, since it is small, will not be analyzed.

4. Isochromatid deletions



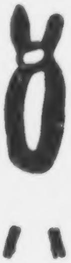
sister union

or



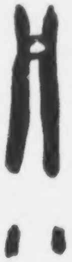
non-union proximal

or



non-union distal

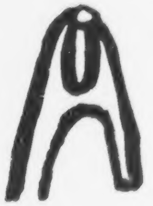
or



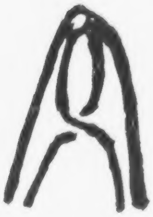
non-union proximal & distal

The acentric fragment is frequently not associated with the deleted chromosome. This can be the most ambiguous of the chromatid-type aberrations since non-union distal will lead to an acentric fragment that is indistinguishable from a chromosome-type terminal deletion. The presence of sister union would confirm an isochromatid deletion, since chromosome-type terminal deletions do not have associated sister union. However, in mammalian cells sister union is uncommon. Also the presence of clearly recognizable chromatid-type aberrations in the same cell as a double fragment would indicate that the double fragment is an isochromatid deletion. In the absence of any confirmatory information, a double acentric fragment should be classified with chromosome-type terminal deletions.

5. Interarm intrachanges



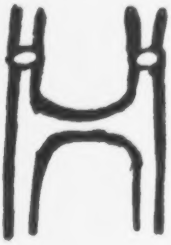
asymmetric



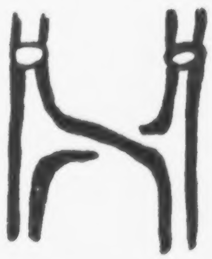
symmetric

There are in fact two forms of both the asymmetric and symmetric intrachanges, but for metaphase analysis only one of each is distinguishable. The symmetric form can be observed since chromatid pairing is maintained.

6. Interarm interchanges (chromatid interchanges)



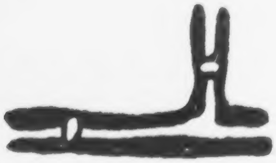
asymmetric



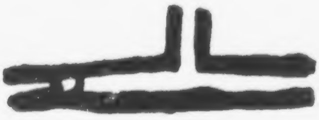
symmetric

These aberrations are the chromatid-type equivalent of the dicentric and reciprocal translocations. However, chromatid pairing allows the symmetric type to be analyzed efficiently, in contrast to the chromosome-type reciprocal translocation.

7. Triradials



or



This aberration can be considered as the interaction between an isochromatid break and a chromatid break to give a 3-armed configuration. There are several possible resulting configurations, but by far the most common are those indicated above.

There are also many additional categories of complex chromatid interchanges, but these occur infrequently, and, to avoid confusion, will not be dealt with here (see Savage [7]).

C. Other Chromosome Abnormalities

1. Shattering

In shattered cells the chromosomes seem to have broken into many small pieces. All the chromosomes can be affected, but usually only a small number are involved. Shattered cells should be recorded separately and not be included in the total number of cells analyzed.

2. Pulverization

This phenomenon is similar to shattering, but usually the whole cell is affected. The chromosome fragments are thin and unwound. There is similarity between such a cell and the chromosomes of an S-phase cell when fused with a mitotic cell (premature chromosome condensation). Pulverized cells should be recorded separately, and not be included in the total cells analyzed.

3. Polyploidy

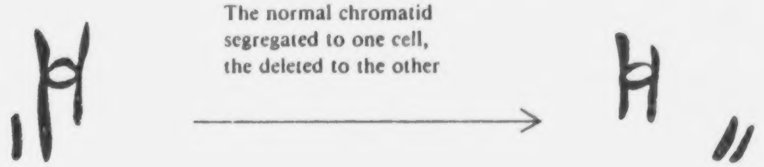
Polyploid cells are occasionally observed. Such cells are recorded separately, and are not included in the total cells analyzed. Aberrations observed in polyploid cells should not be included in the overall aberration frequencies.

D. Secondary or Derived Aberrations

As mentioned in the introduction, the majority of induced aberrations observed at the 1st mitosis in culture will have been derived, as the result of cell division, from chromatid-type aberrations produced in stem cells. The following list shows the most common derived aberrations and the possible primary source. It should be noted that the probability of an induced aberration leading to a derived one is not high, especially when more than one cell division occurs between treatment and observation. Further, the primary source given is not the only possible one, but perhaps the most likely.

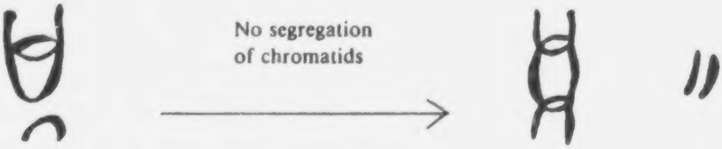
Chromatid-type Primary Aberration	Chromosome-type Secondary or Derived Aberration
Chromatid terminal deletion Isochromatid deletion Incomplete interchange Incomplete intrachange	Terminal deletion

Note: Following two divisions the acentric fragment usually will be lost, leading to cell death or a deleted chromosome without a fragment. This latter often will be detected only by banding.



The normal chromatid
segregated to one cell,
the deleted to the other

Interstitial deletion	Interstitial deletion often only detectable by banding
Isochromatid deletion (only when proximal union)	"Mirror-image" dicentric



No segregation
of chromatids

Chromatid-type Primary Aberration		Chromosome-type Secondary or Derived Aberration
Intrachange 	The normal chromatid segregates to one cell, the abnormal to the other →	Centric ring Asymmetric interchange Dicentric triradial 	One possible segregation gives one cell with normal chromatids, the other with the dicentric →	Dicentric (excluding "mirror-image" dicentrics) Symmetric interchange 	One possible segregation gives the translocated chromatids in the same daughter cell →	Symmetric interchange (reciprocal translocation) 
An important consideration that was mentioned earlier is perhaps best re-emphasized here in the context of derived aberrations. Cells should be analyzed at the 1st metaphase after culture initiation. This is discussed in the section on techniques. Failure to do this can lead to an underestimate of aberration frequency, and to more aberrations being included as derived chromosome-type, since chromatid-type aberrations arising spontaneously during culture will appear as chromosome-type if analyzed at the 2nd culture metaphase.

Recording of Aberrations and Analysis of Cells

All aberration types described above should be recorded separately on a score sheet. For each treatment, the results should be reported as the frequency of each aberration type per cell, and the frequency of aberrant cells for each aberration type, and not as total breaks per cell. For a statistical analysis, it is often appropriate to combine the frequencies of different aberration types: for example, chromatid-type deletions, chromosome-type deletions, chromatid-type exchanges, and chromosome-type exchanges.

One important additional point concerns the recording of cells containing multiple aberrations. If at all possible, such cells should be analyzed and not simply recorded as "multiple aberrations," or abnormal cells, since this latter class causes potentially valuable information to be lost. If a cell cannot be analyzed, it should be recorded as containing too many aberrations to be classified, and not included in the total cells analyzed.

This leads to some comments on which cells should be analyzed. The acceptable method is to scan cells at low magnification. A cell which appears analyzable at low magnification, should be scored under oil immersion. The only reasons that a cell should be rejected from analysis once observed at high magnification are: 1) if it contains so many aberrations that it cannot be completely analyzed, when it is recorded as too many aberrations to classify (as above); 2) if it contains less centromeres than the chosen cut-off point — some individuals score only cells with 46 centromeres, others use 46 ± 2 as their criterion, where either is acceptable, provided that consistency is maintained; and 3) when the individual chromosomes cannot be seen clearly because of considerable overlapping or because nonchromosomal material (e.g., dirt or stain crystals) obscures chromosomes.

The number of cells to be analyzed from any particular individual or group will be variable, and is discussed below under "Analysis of Data."

The slides should be analyzed without prior knowledge of the group to which they belong, i.e., a blind study should always be done. This is particularly important in a population monitoring study. It is usual for the analysis to be shared between several individuals or between two or more laboratories. The study design should be such that possible bias introduced by an individual or laboratory will not influence the overall result. It is further suggested that an aberration observed or suspected by one individual be confirmed or negated by one or more other individuals. It is also highly desirable that a photographic record be kept of all aberrant or suspect cells.

Sometimes additional treatment of the samples has been advocated. It has been suggested that only banded preparations be analyzed. It is recommended here that normally this not be done, since it is very time consuming and, to date, it does not appear that any significant increase in detectable aberrations has been

observed. It can be seen from the aberration types induced that only derived terminal deletions, where the acentric fragment is lost, and reciprocal translocations can be better detected by banding. The increased sensitivity for detection of these classes obtained by using banded samples does not appear to warrant the large additional effort.

We also suggest that a banded karyotype be produced for each individual included in a study. The reason for this is to detect a congenital chromosome abnormality which could affect the analysis. This is not essential but is recommended so that at some later date the analyzer of the cells is not confronted with the information that he had analyzed a translocation heterozygote or other chromosomally abnormal individual without noting it.

This is an overview of the classification and analysis of chromosome structural changes. It cannot cover every possible eventuality, but it attempts to cover the more likely ones.

IV. ANALYSIS OF DATA ON STRUCTURAL ABERRATIONS

In analyzing counts of structural aberration frequencies, the simplest analyses of data on exposed and control groups lead to standard statistical procedures for the comparison of binomial distributions. However, real environmental exposures often may not be representable in such simple terms. The researcher should be prepared to consider any of a number of more sophisticated analytic approaches which are currently available, or to derive new statistical models to represent the particular situation encountered, if standard procedures are inappropriate.

The specification of sample sizes in terms of either numbers of persons or numbers of cells examined is also difficult, since it requires some prior knowledge or supposition of the results to be obtained. Such information will not generally be readily available in most instances of suspected environmental exposures. Some rough estimates and general guidelines are discussed.

A. Analysis

The analysis of collected data will be an attempt to ascertain whether there are indications of prior exposure to either ionizing radiation, chemical mutagens, or both. This is done by trying to rule out chance occurrences as an explanation of any differences observed in the frequency of chromosome aberrations. The raw data on counts and types of aberrations seen should be presented in as much detail as is practical. It should include the numbers of aberrations seen per cell as well as the number of cells with aberrations, for each of the types of aberrations scored. Ideally, the data summary should include sufficient specification of detail so that others may attempt their own analyses of the data, if desired.

Generally speaking, scored chromosome breaks and rearrangements in cultured peripheral leukocytes have been used much more widely as indicators of direct radiation exposure than of low-level chemical exposure. Upon exposure to whole or partial body radiation, the evidence indicates that circulating lymphocytes or their precursors are subject to some fixed probability of receiving "hits" to their chromosomal material. These "hits" will subsequently be observed as structural changes in metaphase preparations, as discussed above. The probability of such "hits" will be monotonically dependent on the radiation dose (though the aberration induction rate also may be affected by dose rate and other potential confounding variables).

For those cells which are affected, a sufficient environmental insult can result in one or more breaks in the complete chromosomal complement. It is generally assumed that all parts of the chromosomal complement are equally likely to be the site of a break. These assumptions imply that the number of breaks in the total chromosomal material of a given cell should be distributed as a Poisson variate with some average occurrence rate, λ , which is a direct function of the degree of intensity of the exposure. That is, the probability of a number, x, of breaks occurring as a result of an exposure which generates an average of λ breaks per cell should be given by:

$$P(x) = \frac{e^{-\lambda}\lambda^{x}}{x!}; \quad x = 0, 1, 2, \ldots$$

At very low levels of radiation exposure, it is unusual to have more than one break per cell, and extremely rare to have more than two. The probability of no breaks is given by:

$$P(0) = e^{-\lambda},$$

and, if the average rate of aberrations is on the order of 1 or 2 per thousand cells, then $\lambda = 0.001$, and $P(0) = 0.999$. That is, almost all cells will be unaffected, and only about one in a thousand cells, on the average, will display one or more breaks. In fact, the probability of 2 or more breaks per cell will be on the order of 10^{-7}. Even for a value of $\lambda = 0.01$, the probability of 2 or more breaks will be on the order of 10^{-4}.

Because of these numerical realities with low-dose radiation exposures, individual cells are classified most commonly as either affected or not affected with respect to whatever type of aberration being scored. Multiple aberrations in a single cell are occasionally seen, but this is not common in low-level radiation exposures, and is very rare in control data. When it does occur, it probably indicates that the data on the individual involved should be examined more closely for the possibility of heavier exposure or other potential confounding influences.

Published data on normal population controls are not extensive. It is usual to exclude persons who report recent or unusual radiation or chemical exposures or recent viral infections from the control group. The control data that are available do not suggest an effect of age or sex on structural aberration frequency. However, because of the current paucity of data on potential confounding variables, good histories should be obtained from all study subjects concerning their past work, medical, and residential experience.

For cytogenetic analysis, a number of metaphase cells will be chosen for scoring, presumably randomly selected from among those eligible for scoring by reason of their adequacy of spread and chromosome count. The number of cells scored will differ from investigation to investigation, depending upon the specific questions that are posed, the heterogeneity of the populations studied, and the degree of precision required for the circumstances at hand. Sample size considerations will be discussed below.

For an individual, therefore, the data will consist of the number of aberrant cells out of some fixed number scored. With a fixed sample size of cells, if the probability of finding an aberration of a given type in a cell is constant from cell to cell within the sample, and if the results on different cells within the sample are independent of one another, then the count of the number of cells with aberrations should follow a binomial distribution with parameters n = the sample size and p = the true proportion of aberrant cells in the blood of the individual sampled. Data are available (unpublished) which indicate that these assumptions are reasonable, at least for data from controls and those with low-level radiation exposures. For each individual scored, the fraction of cells which are aberrant is an estimate of the true proportion of aberrant cells within that person's population of circulating lymphocytes and that observed fraction will be subject to binomial variability. The task at hand will be to compare the collection of observed proportions, and to determine whether they are elevated, on the average, in the exposed sample relative to the controls.

The most powerful analysis (in a statistical sense) results when one can pool the data across individuals within exposure groups and compare the frequencies of aberrant cells between the exposure groups using the total number of cells examined in each group as the denominator for the overall estimate of aberration frequency. In order to do this, one must be assured that the amount of variability in the proportion of aberrant cells observed from person to person does not exceed the amount that would be expected in repeated sampling from a *single* binomial distribution. The usual chi-squared goodness-of-fit test for categoric data is not likely to be very sensitive to variation in proportion affected; Fisher's variance test is recommended as a much more sensitive alternative (see, for example, Cochran, 1954, p 417 [8]).

If the data are compatible with a single aberration frequency within each exposure group, then one of the statistical techniques for comparing two single binomial frequencies would be appropriate. The data can be displayed in a 2x2 table as follows:

	Exposed	Not Exposed	Total
Abberrant cells	a	b	a + b
Nonaberrant cells	c	d	c + d
Total cells	a + c	b + d	N
Proportion aberrant	$\frac{a}{a+c}$	$\frac{b}{b+d}$	

We want to determine whether the observed proportion in the exposed group, $\frac{a}{a+c}$, is sufficiently greater than the observed proportion in the control group, $\frac{b}{b+d}$, and that the difference is not likely to be due to chance. (Of course, if $\frac{a}{a+c} < \frac{b}{b+d}$ then no further statistical treatment is necessary, unless there are other factors to be taken into consideration.)

Again, the Cochran article lays out rules of thumb for appropriate testing. In general, if the smallest expected value is less than about 5, Fisher's exact test should be used (see, for example, Siegel, p. 96 [9]). Otherwise, a normal approximation is usually adequate. The square root of the usual (uncorrected) chi-squared statistic is probably the simplest way to calculate the appropriate normal statistic.

That is,

$$z = \sqrt{\frac{(ad-bc)^2N}{(a+c)(b+d)(a+b)(c+d)}}$$

is approximately distributed as a standard normal variate; and if it turns out to be greater than 1.645, for example, then the proportion of aberrant cells in the exposed group would be declared greater at the 5% level of statistical significance than that in the control group.

Of course, the foregoing discussion applies to only the simplest situation. If there is heterogeneity within either or both study groups, or if other potential confounding factors exist, or are thought to be exerting an influence, then more complex analytic procedures will have to be considered. Sometimes, the foregoing simple situation can be approximated by stratifying the study groups into relatively homogeneous subsets, subsequently combining the significance testing results by some appropriate technique (again see the Cochran article [8], or Fleiss, Chapter 9 [10]). In situations in which other variables must be accounted for (e.g., age, sex, time of exposure, actual exposure estimate, etc.), a variety of techniques are available, including logistic regression (e.g., Cox,1970 [11]), multiple linear regression (e.g., Evans, et al [6]), and many others (e.g., Bishop, et al [12]).

If, particularly for chemical exposures, it is thought that an individual's population of lymphocytes is actually a mixture of exposed and unexposed cells, then some estimate of the parameters of the mixed population would be a desirable first step in the analysis (see reference [13]). If there is reason to believe that the binomial parameter varies from person to person in some specific stochastic manner, then it would be appropriate to consider modeling the results with one of the so-called "contagious" or compound distributions (e.g., Johnson & Kotz [14]).

If a difference is found between the putatively exposed group and the controls, either in terms of frequencies of cells with aberrations or frequencies of aberrations per cell, then further analysis will be required to investigate whether a "dose-response" relationship can be established, and whether interactions exist with other potential confounding variables.

B. Sample Size Considerations

The size of available samples will have an important effect on the conclusions drawn, particularly if the results appear to be negative, for in that case we will want to be able to rule out with some degree of assurance the possibility of having missed an effect. The ability of a statistical test to rule out a difference of a given size is called the "power" of the test.

In order to estimate necessary sample sizes, one must specify the significance level at which the test will be done, the size of the difference (in proportion of affected cells, in this case) which would be of biologic importance or interest, and the desired degree of assurance to rule out the existence of a difference as large as, or larger than, that specified. Figure 1 shows the results of some calculations of the approximate sample sizes needed for comparing two proportions under a variety of circumstances. The bottom axis shows various potential values for the true aberration frequencies in the control group (e.g., p_1). Then, assuming a test will be done at a 5% level of significance, the graph indicates the approximate sample sizes required for each group in order to rule out an aberration frequency in the exposed group ($p_2 = kp_1$), and to do so with a probability of 0.80.

For example, if an observed frequency of about 1% were expected in the control group (as might be the case if all structural aberrations were being considered), and it was desirable to detect a threefold increase in the exposed group ($k = 3$), then about 600 cells in each group would be needed to give 80% assurance that such a difference would be detectable at a 5% testing level. On the other hand, if the aberration frequency were expected to be only 1/1,000 in the control group (as might be the case with dicentrics and rings), then about 3,500 cells in each group would be needed in order to detect a fourfold increase in the exposed group, with 80% assurance. (To guarantee 90% power, the sample sizes determined from this graph should be multiplied by about 1.5.)

The foregoing estimates were calculated on the assumption that the total sample within both the exposed and control groups could be pooled for analysis. It was also assumed that the two groups would be equal in size. Since either or both of these assumptions may be inappropriate in a particular case, the estimates given should be taken as indicating only the order of magnitude of the effort which may be necessary in a particular instance.

The design of a study, and, in particular the selection of controls, should be given careful consideration, taking into account the circumstances to which the investigators are responding. In some situations, the resources available would be utilized best by having fewer controls than exposed. In others, it may be necessary to have multiple controls per case in order to assure adequate power. The extremes, one cell per person, or the entire sample from one person, obviously are to be avoided; but the optimal intermediate point cannot be specified in general and must be determined on pragmatic grounds in response to the particular circumstances being confronted. The only general principle which should be followed is to have concurrent controls adequate to rule out laboratory artifacts or time factors as explanations for any differences observed.

Size (n) of Each Sample Necessary to Detect
a k-Fold Increase in the Exposed Group Over
the Control Group for Various Control Frequencies

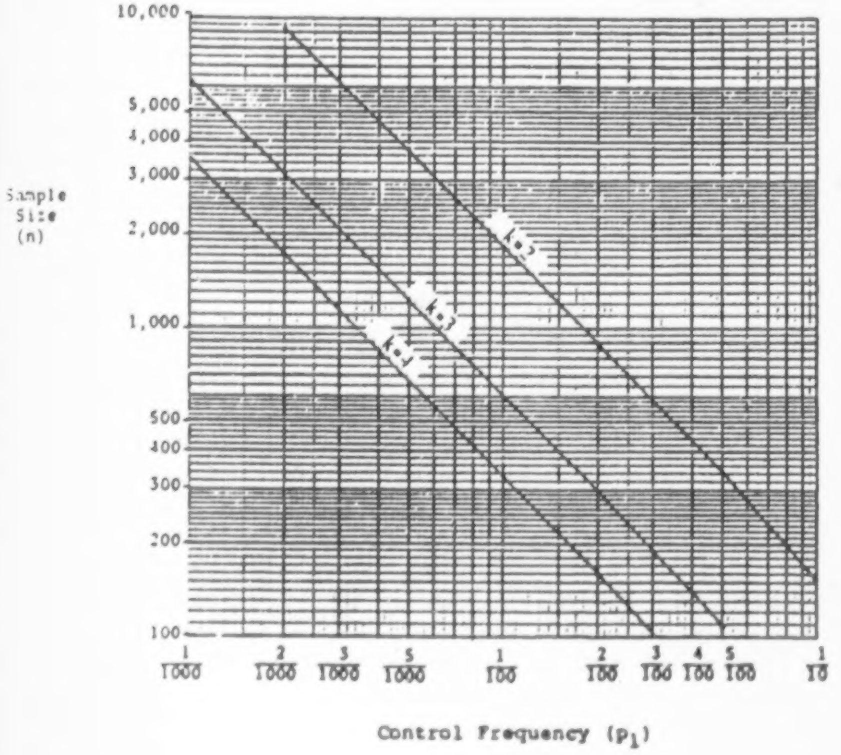

Fig. 1.

The quantification of structural aberrations (or sister chromatid exchanges) presents an opportunity which is not common in research and which potentially can be exploited to mitigate the absence of the prior knowledge required for precise sample size determination. If the total number of cells to be examined is allocated toward fewer cells per person and more persons in the initial investigation, this should leave a potential bank of cells for each individual which remain unexamined, but which are available to increase the sample size in either exposed or control group, if that should be found desirable after an initial analysis. Furthermore, such additional data acquisition can be done with a minimal expenditure of effort and cost.

One other general problem is the question of the degree of specificity with which an *individual's* aberration frequency can be estimated. This, of course, will be the question of interest once an elevated aberration frequency has been shown for the exposed group as a whole. In general, it requires considerable data to estimate a small frequency within narrow limits. For example, if 100 cells from an individual had been examined and *no* aberrations had been found, one could only estimate his true aberration frequency as less than 4% at the 95% level of confidence. With 200 normal cells, the upper 95% confidence limit on the true proportion is 2%, and it is not until about 375 normal cells are examined that 95% assurance can be given that the true rate in the individual examined is under 1%. This would represent an enormous investment of technician time, and in many circumstances, would not be considered justifiable from a cost viewpoint.

V. METHODS AND PROCEDURES FOR THE ANALYSIS OF SCEs IN HUMAN LYMPHOCYTES

As indicated above, the type of lesion induced in the genetic material will influence the cytogenetic alteration produced to a large extent. SCEs are more pronounced following exposure to those agents that form covalent adducts to DNA or chromatin, or otherwise induce distortion of chromatin structure relative to those agents that directly break the DNA backbone. Thus, although there may be an overlap between those agents that produce both aberrations and SCEs, both cytogenetic end points should be included in any population study. As an illustration, a population study involving known radiation exposure might be expected to yield an increase in aberrations. The use of SCEs in the same individuals would be useful to determine potential exposure from confounding factors such as medication or smoking. This section will address those points pertinent to the methodology for the evaluation of SCEs in human lymphocytes.

A. Blood Collection and Cell Culture

Whole blood obtained by venipuncture should be mixed with heparin, acid citrate, or another appropriate anticoagulant. This mixture can be stored between 4-37 °C for several days prior to culture, but this is not desirable. Lymphocyte loss, reduction of mitogenic response, and possible selective loss of SCE-forming lesions may occur during storage. Therefore, cultures should be established within 24 hrs, if possible. A white blood count and smear for a differential should be made from the blood sample just prior to establishing the culture. These end points serve as indicators of abnormally high or low lymphocyte counts which may influence the frequency of SCEs.

For the analysis of SCEs, it is imperative that each laboratory establish a standard-lymphocyte culture procedure. The detailed procedure may vary among laboratories but all should adhere to some basic requirements. Bromodeoxyuridine (BrdUrd) can induce SCEs in human lymphocytes, and with the culture conditions employed for most SCE studies, this induction is dependent on the ratio of the BrdUrd concentration to the number of lymphocytes per culture, as shown by Carrano et al [15]. This ratio should be kept as invariant as possible. In order to insure this, each laboratory should establish its own SCE induction curve for BrdUrd using a minimum of four individuals. In general, the frequency of SCEs will rise sharply at low ratios of BrdUrd to lymphocytes but may stabilize at higher ratios. Thus, each laboratory should select a ratio which is optimal for its conditions and maintain this as standard procedure. Selection of a ratio which is in the stable region of the curve may minimize the SCE variation produced by fluctuations among individuals in lymphocyte counts or in mitogenic responsiveness. Another factor to consider is the minimization of intra- and inter-individual variation. Each laboratory should select those conditions which minimize these sources of variation.

Selection of culture medium, serum type and concentration, whole blood vs purified lymphocyte cultures, and duration of culture are somewhat flexible and should be based upon historical experience. It is recommended that the serum lot be pretested for its potential to support lymphocyte growth and for its reproducibility of baseline SCE frequencies in at least two longitudinal control individuals (i.e., the same individuals repeatedly sampled with time). If feasible, the same serum lot should be used for each population study. The duration of the lymphocyte culture should be one that yields a high percentage of 2nd division mitoses. Each of these variables should be standardized prior to any study. Exposures of the cultures to other than yellow or red light should be avoided.

A minimum of two cultures should be established for each individual, which can be harvested at either the same or different times. The primary purpose of the replicate cultures is to insure a backup in case of culture or other technical failure. They may be used also to estimate culture-to-culture variation, if this is warranted. When a large number of cultures are processed, the inclusion of samples from longitudinal controls is important. Further, it is good practice for each laboratory to sample its longitudinal controls periodically to insure that the procedures remain satisfactory. Occasional addition of a positive control (e.g., an individual on chemotherapy or in vitro treatment with mitomycin-C) is useful to insure that the culture conditions allow for cellular responsiveness in terms of SCEs.

B. Preparation and Scoring

At the appropriate culture time, the cells can be arrested in mitosis by a 2-4 hr treatment with Colcemid, colchicine, or other suitable spindle inhibitor. Care must be taken to insure that the arresting agent does not induce SCEs, particularly if the longer treatment times are used. Any of the routine metaphase cell preparation methods are satisfactory. Several slides should be prepared from each culture, and the remaining cell pellet stored for future reference in absolute methanol:glacial acetic acid (3:1) at 4°C or lower. The slides can be stained for analysis by fluorescence alone [16], fluorescence plus Giemsa [17], or a reproducible variation thereof. The sister chromatids should be well differentiated, i.e., there should be a high contrast in staining intensity between the two chromatids, and there should be a minimum of staining debris. Once a staining procedure has been standardized and adopted, it should be used throughout the course of the study.

Only well-differentiated metaphases should be accepted for scoring. The slides must be coded as in the breakage studies, so that data collection is done in a blind fashion. The coded slides can be scanned under low magnification (100-200X) and selected for scoring on the basis of well-stained sister chromatids and an adequate number of chromosomes in the metaphase. Assuming that large chromosomes are not preferentially lost or gained during cell preparation and that SCEs are evenly distributed along the length of the chromosome, cells with other than 46 chromosomes can be analyzed. It has been established in at least two laboratories (unpublished data) that cells with 41 or more chromosomes are acceptable for SCE analysis, i.e., there appears to be no significant difference in the mean SCE frequency for an individual if cells with 46 vs 41 or more chromosomes are accepted. The experienced cytogeneticist can distinguish a cell with this number of chromosomes under low magnification. SCEs are counted for each chromosome in the cell with the final results tabulated as the number of SCEs per chromosome, or as the number of SCEs per diploid cell (i.e., the number of SCEs per chromosome X 46). The precise number of cells to be scored per individual will ultimately depend upon the desired relative sensitivity for the study.

Figure 2 illustrates the method for scoring. The exchange of stain must be reciprocal, i.e., a darkly stained region on one chromatid must be accompanied by a light staining region in the reciprocal region of the sister chromatid. It is not necessary that the entire chromatid width be involved in an exchange (Fig. 2H). Exchanges of stain occurring at the centromere (Fig. 2F) should be included as an SCE unless there is an obvious twist of the chromatids.

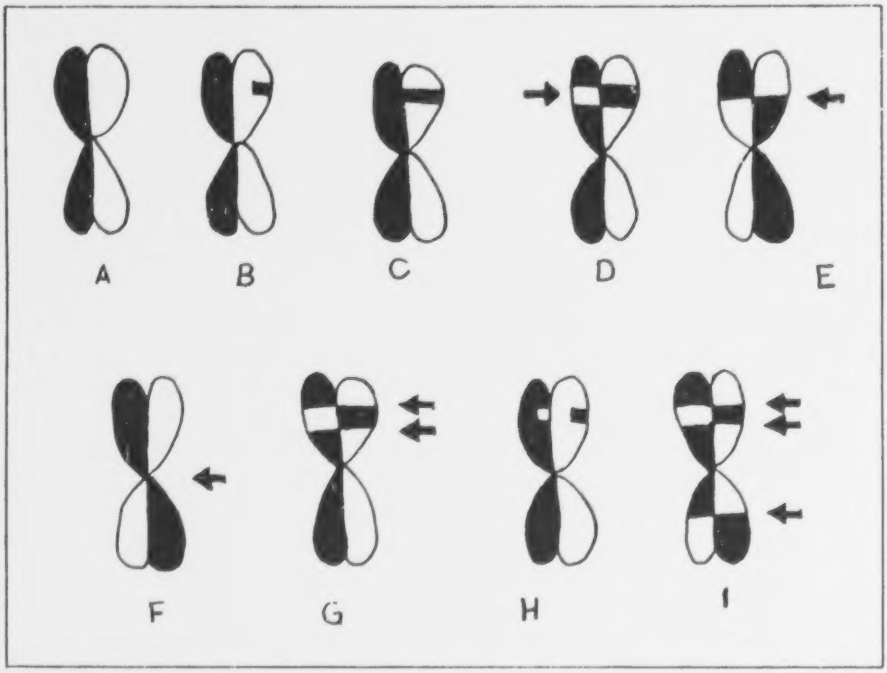

Fig. 2. Schematic representation of chromosomes differentiated for SCE analysis. The dark region represents unifilar substitution with BrdUrd, and the light region represents bifilar substitution. A) No SCE: complete differentiation of the sister chromatids. B) No SCE: incomplete differentiation or staining artifact. C) No SCE: staining artifact or possibly replication through less than 2 complete DNA synthetic periods in the presence of BrdUrd. This pattern should not be observed in metaphases from short-term lymphocyte cultures, if BrdUrd is added at the time of mitogen stimulation. D) No SCE: probably replication through more than 2 DNA synthetic periods in the presence of BrdUrd. E-I) SCEs are indicated by arrows. E) Single SCE. F) Single SCE at the centromere. G) Two SCEs. H) Two SCEs: reciprocal exchanges not covering the complete width of the chromatid I) Three SCEs.

C. Statistical Analysis of SCE Data

There are at least 2 statistical questions which arise as the result of the analysis of 2 or more cohorts. First, are there significant differences between cohorts; and second, does a specific individual in the test cohort differ significantly from the control cohort? As stated previously, the use of concurrent controls is mandatory and these should also be compared to historical controls. In order to optimize the statistical analysis, knowledge of the distribution of SCEs both within and among individuals would be useful. At the present time, such information is preliminary but suggests that no formal statistical distribution can adequately describe the within individual SCE measurements. The problem appears to be the existence within individuals of outlying cells, i.e., lymphocytes with very high SCE frequencies. The data for one population study do suggest, however, that the distribution of individual SCE means, at least in a control cohort, are normally distributed (Carrano and Moore, unpublished results). Obviously information on the distributions for other populations is needed before any statistical tests can be recommended as generally applicable. Until such time, each investigator should determine, for his own study population, the degree of homogeneity of the individuals within a cohort and then apply the appropriate statistical tests. Any analysis of data should consider the effects of confounding variables.

VI. SIGNIFICANCE OF ABERRATIONS AND SCEs

We are all exposed more or less constantly to agents which are capable of damaging the genetic material of our somatic or germ cells, and there are many mutagen-exposed human populations in which increased chromosomal breakage has been documented. These include the Hiroshima and Nagaski atomic-bomb survivors and numerous other radiation-exposed populations. Chemical exposures in human populations have been much less well studied genetically and cytogenetically, and most of our assumptions about these effects of chemical mutagens are derived from the radiation studies. Even when the exposure has been to a known mutagen (as ionizing radiation) at high doses (as in Hiroshima and Nagasaki) with considerable residual chromosomal damage, no increases in spontaneous abortion or birth defects have been found to date, and no heritable chromosomal abnormalities have been demonstrated. Our assumption must be not that such effects do not occur, but simply that their magnitude is very low, indeed.

Further, in human populations, no associations have been definitively drawn between those individuals with induced breakage and the subsequent development of cancer. This is true even in Japan, where thousands of persons have been shown to have chromosomal aberrations of radiation origin. Stable translocations and other aberrations have been shown to be useful in dosimetry assessments at high doses. Thus, although the presence of the chromosome breakage in the lymphocytes of mutagen-exposed persons is at times a marker of exposure, it is not by definition a harbinger of cancer for the carrier individual.

The two-step cancer hypothesis of Knudson et al., [18], however, suggests that not all individuals may be at equal risk of developing cancer. According to the hypothesized first step, some individuals are born with an inherited predisposition to cancer. These include: 1) persons who carry the autosomal dominant genes involved in disorders like retinoblastoma, Wilms tumor, and some forms of breast cancer; 2) persons who are affected with the autosomal recessive chromosome breakage syndromes, like Fanconi anemia, Bloom syndrome, and ataxia telangiectasia; and 3) persons with chromosomal anomalies of the karyotype, such as trisomy 21; or the recently described translocation family with a t(3:8) in which there exists an 87% risk of renal cancer by age 59 in carriers [19]. The second step of the hypothesis involves a somatic mutation of environmental origin (radiation, chemical, viral).

Further, we have a nonhomogeneous response to environmental mutagens in our species, with some repair-deficient persons (XP, AT), some immunologically underresponsive persons, etc., at increased risk of carcinogenesis for genetic reasons. These individuals may have an increased tendency to respond with enhanced chromosome breakage to environmental exposures. The identification and management of such genetically at-risk persons is a problem of major proportions for those concerned with the health effects of mutagens.

So, while we deem chromosomal aberrations as undesirable, as we consider induced mutations generally to be deleterious, we are unable to use them to predict specific human health effects in the individual. But, considerable evidence has accumulated that, at least for physical mutagens, chromosomal aberration frequencies may be reliable as biologic dosimeters for some individuals, but even more useful for subsets of a population exposed to various doses of a mutagen. This utilization of chromosomal aberrations as a biologic dosimeter has been shown to be valuable in radiation exposures, for both immediate studies of acutely exposed persons and many years after the acute high-dose exposure. Certain types of aberrations have proven particularly sensitive as indicators of dose, and these tend to be the aberrations which are rarely seen spontaneously, i.e., under "control" conditions. Such aberrations include, for example, dicentrics, rings, and balanced translocations.

This raises the question of the fate of various types of aberrations in cell division. Ample evidence exists in numerous systems that many sites of damage are repaired, though the mechanisms of this repair process in human cells remain to be elucidated. Nonetheless, the simple types of aberrations, such as chromatid breaks and deletions, are generally useful in acute exposures, much less valuable long after exposure, and of intermediate utility in chronic, low-level exposures. Some of the more complex aberrations may be eliminated during cell division (mitotic or meiotic), because of difficulties at the time of spindle formation or at other times; but they may nonetheless be more useful in biologic dosimetry than their simpler counterparts because they are so rarely seen normally, and because they are at times able to survive at least a modest number of in vivo or in vitro cell divisions. The long-lived nature of some lymphocyte subpopulations enables us, then, to analyze for rings, dicentrics, and translocations with dose questions in mind. In particular, the balanced translocations may be of help in such studies, since such translocations are often stable more or less indefinitely.

Another phenomenon requires comment, that of the amplification of subpopulations of aberration-bearing lymphocytes. The increase in frequency of cells which all bear the same aberration has been repeatedly documented in radiation-exposed populations. Reasonably this has been referred to as in vivo clone formation. Again, we cannot draw conclusions regarding the health of the clone formers, though we assume this phenomenon to be undesirable for the patients.

To this point, we have been concerned with somatic cell chromosomal aberrations. Agents which induce this kind of damage reasonably may be regarded as capable of doing so in germ cell chromosomes as well. However, even in the Hiroshima and Nagasaki populations, with all of their induced somatic cell aberrations, no consistent heritable aberrations (translocations, inversions, or the like) have been demonstrated to have been induced and transmitted to the F_1 generation [20]. Our concern for such F_1 effects must continue, but realistically the magnitude of the clastogenic effort is unlikely to be very great, based on what we have not seen to date, and somatic cell clastogenesis must be our primary concern.

The phenomenon of sister chromatid exchange has, we now believe, a different biologic, and therefore a different clinical significance from that of chromosomal aberration formation. Based on in vitro studies of recent years, largely with Chinese hamster cells, SCEs appear to correlate better with specific locus mutations than with clastogenic effects. Further, SCEs are more sensitive to chemical mutagens than to physical mutagens, as has been shown in studies with CHO cells exposed to a wide range of known chemical and physical mutagens including exposures to radiomimetic compounds, such as bleomycin. Assessment of in vivo SCEs is in its early stages, with only a few such human studies having been conducted, as discussed above. For these reasons, the Panel suggests: 1) that the usefulness of SCE studies in human populations is likely to prove to be a sensitive measure of exposure to chemical mutagens; but, 2) that such studies are in their formative, or developmental, stages and must be interpreted with caution. However, the Panel does recommend that such studies be done in instances of exposure of humans, acutely or chronically, to known or putative mutagens, with careful attention being paid to the inclusion of adequate controls. The same concerns described above for chromosomal aberrations, in terms of the 2-hit cancer hypothesis, would be applicable for SCE induction, and SCEs show promise of being an excellent reflection of point mutation in vivo as in vitro. Evidence exists for SCE formation in relation to repair and repair deficiency, but the mechanism(s) of SCE formation are not clearly understood at this time.

Throughout the discussion in this Chapter we have dealt essentially with aberration and SCE studies in the peripheral blood lymphocytes of exposed humans. Other tissues, such as bone marrow and skin, or even gonial cells, at times may be useful to study. But, for routine screening on a population level, there now seems little reason to go beyond the peripheral blood cell studies, ideally done under well-controlled conditions, with specific questions to be answered. We recognize full well, however, that such studies may be done at times when the agents and the doses are ill defined. Under those conditions our suggestion is that suitable control groups be simultaneously studied, with all microscope work being done blindly, i.e., without investigator knowledge of the putative exposure status of the person whose cells are being examined.

SECTION I

INTRODUCTION

In considering reproductive failure in relation to environmental exposures, we have defined reproductive failure (or, more properly, dysfunction), as an increase in one or more of a list of undesirable end points. There are shortcomings to this approach: many end points are not independent, and an increase in one deleterious end point, may be the result of decrease in another, e.g., neonatal mortality rates may increase as the late fetal death rate decreases and very low birthweight babies are born alive. Still, we content ourselves for now with the simplest possible definition.

For the exposure, we have hardly even attempted a definition. We simply imply that an adverse exposure is some physical or chemical contaminant of the physical environment (air, water, food or workplace). Usually, we visualize a concentration in one or several geographic areas, or in the workplace.

Section II provides the list of end points. Then, Sections III, IV, V, VI and VII describe principles and methods of study, and decision making. Section III discusses general statistical problems, especially relevant to investigations of the effects of environmental exposures. In Section IV, we set out the immediate steps usually taken by an investigation, alerted by a potential problem area. This account, based on the actual procedures adopted by the Center for Disease Control, emphasizes the uses and limitations of easily accessible sources of information. A description of some of these is included. The transition from what we term Level I studies, based on easily accessible data, to more prolonged and costly investigations (Level II studies) of a wider range of end points seems to be a point of decision making, and in Section V we discuss guidelines for movement from Level I to Levels II and III. Section VI is a guide to the design of epidemiologic studies, emphasizing considerations that may lead to a choice of case control or cohort approaches, the selection of controls, and the control of bias. Section VII gives a brief review of long-term follow-up studies (Level III) that might be conducted.

In Section VIII, nine end points were selected for further attention to provide an outline of current methods of study. Section IX is a critical review of publications dealing with environmental exposures and reproductive failure.

In this introductory section, five general themes will be introduced:

1. The distinction between investigating a *cluster* of adverse effects, as opposed to a supposedly hazardous *exposure*.
2. The level of the investigation, in terms of cost, complexity, and the time required for completion.
3. Some special problems of specifying exposure, whether by measures based on individuals or by measures based on populations.
4. The basis for decision making, and the considerations, scientific and otherwise, that enter into the process.
5. The interrelationships between findings based on reproductive failure, somatic cell changes, and in vitro tests of mutagenicity.

1) A Cluster of Effects Compared to a Hazardous Exposure

Residents of Alsea, Oregon, and later of Cape May, New Jersey, reported to journalists, public health officials and others, that spontaneous abortion (miscarriage) was occurring "too often," among pregnancies in their localities. Cape May residents also mentioned an excess of births with hydrocephalus. Although in both these examples, the residents themselves linked the apparent cluster of effects to an environmental exposure (pesticide), still the stimulus for concern was a suspected excess of reproductive problems. We will call this type of situation a "Cluster."

By contrast, residents of the Three Mile Island area, and those in the neighborhood of toxic wastes, provide an example of an exposure-provoked situation, an "Exposure."

Thus in Cluster situations, the investigation is provoked by some real or apparent excess in the occurrence of an adverse reproductive end point; in Exposure situations, an episode involving known or suspected toxic substances has occurred, and adverse effects are anticipated. Cluster type situations and Exposure type situations present unique problems to the investigator, and each may call for a different public health response.

With Cluster situations, the relevant outcome is (presumably) known or suspected. The first task is to determine the population at risk and to decide whether the *observed* concentration in space and time of the outcome (which constitutes the "cluster") represents a meaningful departure from the *expected* distribution in space and time. The second task, especially when there is no clue as to the cause, is to know which questions to ask in search of the cause.

With Exposure situations, it may not be obvious what outcomes are salient for evaluating whether effects have occurred. Health studies, lacking a targeted end point, become expensive and inefficient. Although in general, the methodologic problems are similar in the two situations, some arise particularly in Cluster situations, and in some Exposure situations, as will be discussed later.

2) The Level of the Investigation

We define three levels of investigation: *Level I* is based on easily accessible, routine records. The investigation will usually be carried out with speed and economy; it will seldom involve case examinations or special questionnaires (although clinical confirmation of supposed 'cases' is not excluded). By definition, end points that are not routinely examined (for instance, sperm studies) or recorded (spontaneous abortions) will not be studied.

Level II includes short-term purposeful epidemiologic studies, either case control or cohort. Investigations of a wide range of end points (including somatic cells) can be entertained.

Level III. This category is reserved for investigations the results of which cannot become known until months, or years have elapsed, following the initial stimulus that provoked the investigation.

The level does not describe the statistics or the design. Thus, in Level I, the investigator will usually be content to compare rates of incidence or prevalence in the suspicious population with expected rates generated from some other population, but the use of case control or cohort design is not excluded. Level II studies may be either cohort studies (in the sense that an exposed group is followed) or case-control studies (in the sense that an affected group is explored in terms of previous experience), but in either case, the end points of interest have already been recognized. In Level III studies, there can be no immediate answer, but the flagging of certain individuals or groups may in time enable the inquiry to be completed. This type of activity may have particular importance in discovering associations between somatic cell findings and subsequent morbidity and mortality. Models for computerizing and storing data for such prospective studies are described later.

Moving an investigation from one level to the next involves making decisions; some of the considerations to be weighed are outlined under (4) below, and discussed more fully in Section V.

3) Defining Exposure

Whereas many useful end points of reproductive failure are reasonably well defined, the same is seldom true of the exposure. As discussed later, the exposure is often poorly defined.

a) There may be multiple exposures. Typically in both the occupational environment (e.g., the chemical industry), and in the vicinity of toxic waste (Love Canal), the population "at risk" has been exposed to a range of chemicals and a range of levels of exposure for each. We do not know if one, or several of these, or even an interaction between two or more, is likely to be responsible for the effects.

b) Measurement of the environmental exposure: If the exposure happened some time prior to the investigation, it may be difficult (or impossible) to discover either the nature or dose of exposure. Ambient pollutants are often transient; pathways and doses of exposures in the soil or water may vary over time in the same location. Dosage levels may vary from place to place, even within one area or plant. Exposures which are not detectable by current measurement techniques may not be without effects. Breakdown products may be the responsible agent and may be difficult to measure.

c) Measurement of exposure to the individual: Ideally, one wants to measure levels of exposure to the individual; this might be obtained through badges worn during all periods of exposure. Often, noninvasive biochemical tests are not available. Other effects of exposure (e.g., chloracne on exposure to dioxin) might serve to indicate an exposed group; however, those health effects are unlikely to serve as surrogate measures of exposures for studies of reproduction.

d) Exposed populations: In many instances, there are no measurements of exposure to the individual, either because effects are being studied long after a transient exposure occurred, or because there are not techniques to measure exposure in the individual and/or the immediate (e.g., home) environment. The investigator resorts to announcing that a population (e.g., town, a factory) is "exposed." This approach may result in misclassification of the study population; some "exposed" individuals are not truly exposed. Misclassification will have the effect of reducing the chance that a study will detect an association between exposure and an end point.

Note that studies limited to comparisons between communities will also suffer if not only the exposures but also the outcomes are treated as group phenomena. This is because individuals within one community may differ considerably in characteristics known to effect the end point (for instance, smoking and birthweight). If these characteristics are not considered, they may lead to false inference in comparing the communities.

4) The Basis of Decision Making

The decision to initiate an investigation, to pursue it more deeply, to pronounce a relationship as present or absent, and to act accordingly, are matters that depend only partly on the scientific community. Nevertheless, these practical considerations must concern us. The statistical section has, therefore, stressed the limits of inference and the areas of uncertainty which will generally remain at the end of most investigations. We have preferred the perspective of an anxious community, employer or public health agency, rather than the perspective of an experimentalist. The experimentalist is often ultra-conservative. He requires the outcome of an experiment to provide strong reason to reject the null hypothesis (setting his chances usually at 1 in 20 that this will occur by chance), while he is less concerned at falsely accepting the null hypothesis (setting his chances typically at

1 in 5 that this will occur by chance). The community is not neutral: interest is focused on a possible excess of adverse outcomes and there is extreme concern that a relationship that is really present not be missed.

Bearing in mind these concerns, we have created tables in Section III that attempt to express the meaning, as well as the limits of inference, that can be derived from the statistical tests. We conclude that the most accessible statement to convey the limits of inference is often effect size. Thus, "the investigation is able to rule out as extremely unlikely, a sixfold rise in such and such outcome . . ." may be an intelligible and useful statement.

We envision that a decision-making body would include nonscientists, and would be concerned not only with probabilities and risks of adverse outcomes, but also with the nature of the outcome under discussion; its physical, emotional and financial cost to parent, offspring, and community (the "*burden*"). In the discussions that follow, the choice among end points for study is discussed mainly from the points of view of accessibility for Level I, frequency, reliability of diagnosis, and usefulness as a sensitive end point. At the point of decision making, burden takes on crucial importance. Thus, a modest effect size (say doubling) involving mortality or severe retardation, may outweigh a larger effect (fourfold) involving miscarriage. These issues are not considered further: they go beyond our present brief.

5) The Interrelationships Between Reproductive Failure, Evidence of Somatic Cell Effects, and In Vitro Tests of Mutagenicity

This topic is introduced here mainly to emphasize its importance, and the lack of knowledge in the area. Should decisions on the existence of effects, as judged by reproductive failure, consider at the same time undesirable effects of a substance on somatic cells of exposed individuals or in in vitro tests? What does evidence for the one indicate about the other? A preliminary approach would be to select a number of agents, and compare their known or suspected properties in terms of each of the three areas of this report. A table of this kind could serve as a basis for useful suggestions as to the need, in Level II and III investigations, for studying a spectrum of epidemiologic and biologic effects.

SECTION II

INDICES OF REPRODUCTIVE FAILURE

We set out below a list of potentially useful end points, that might be studied in connection with reproductive failure or dysfunction. Although this list indicates the wide range of outcomes which could be used, it is not all-inclusive. It is by no means clear how these end points relate one to another, nor whether changes in one will always be accompanied by changes in another.

The list more or less follows a biologic chronology. More detailed discussions on nine selected end points (shown with an * on the table) are given in Section VIII. In Section III, information relating to expected frequencies and sample sizes are shown for some end points. A dagger (†) indicates the suitability of the end point for Level I studies.

List of End Points:

1. Sexual dysfunction: libido; potency
2. *Sperm abnormalities: number; motility; shape
3. *Sub-fecundity: abnormal gonads, ducts and external genitalia; abnormal pubertal development; infertility of male or female origin; amenorrhea; anovulatory cycles; delay in conception
4. Illness during pregnancy and parturition: toxemia; hemorrhage
5. *Early fetal loss (to 28 weeks): morphology; karyotypes
6. †Late fetal loss (after 28 weeks) }
7. Intrapartum death } perinatal death*
8. †Death in first week }
9. *†Decreased birthweight
10. †Change in gestational age at delivery: prematurity; postmaturity
11. *†Altered sex ratio: in fetal deaths; at birth
12. †Multiple births
13. *Birth defects: major; minor; mutations
14. *†Chromosomal abnormalities: in fetal deaths; at amniocentesis; in perinatal deaths; in livebirths
15. †Infant death
16. †Childhood morbidity
17. *†Childhood malignancies
18. Age at menopause

Interrelations Between End Points

It is difficult to anticipate the spectrum of outcomes associated with putative environmental hazards for which there are no previous observations to provide at least tentative working hypotheses. Agents are known which induce *specific effects* upon developmental abnormality only in one organic system, but without marked effect upon other adverse outcomes. Yet such agents may also have effects that would be difficult to predict on the basis of known physiologic effect (e.g., the reported association of congenital heart defects in infants born to women exposed to maternal female sex hormone during pregnancy). Many embryotoxins and other reproductive hazards may be expected to result in multiple adverse reproductive outcomes. Agents resulting directly in disordered embryogenesis sufficient to impair fetal viability (and thus increase embryonic and fetal deaths) are also likely to be associated with increased frequency of structural defects in the fetuses which do survive gestation. Variations in outcome within an exposed population exposed to such known teratogens as rubella, thalidomide, etc., may result from differences in individual maternal or fetal susceptibility to the agent, to variation in dose of exposure, and to differences in timing of exposure during gestation.

Similarly, agents or biologic factors with putative effects upon the karyotype are likely to result also in increased fetal death and in increased rates of malformations associated with various cytogenetic syndromes in those that survive. But again, most agents identified to date which result in fetal deaths and birth defects do so without any observed effect upon the chromosomes, at least in terms of trisomies, monosomies, etc. While all generalizations in this area are subject to some qualifications, for the most part a suspect agent to which there is preconceptional exposure is likely to manifest through *mutagenic* mechanisms and no *consistent* pattern of *structural defects* is likely to be observed. Thus, an observed cluster of specific congenital abnormality, if attributable to an environmental insult, is likely to have resulted from one acting during gestation, not from preconceptional exposure.

There is also the theoretic possibility that an environmental agent associated with embryonic and fetal death or congenital malformation may act by postponing the time of embryonic or fetal death (or by inhibiting it altogether); in such a case, it would not be increasing the actual incidence of such events, but rather enhancing the likelihood of their recognition.

SECTION III

STATISTICAL ISSUES

Some methodologic problems are commonly encountered in investigations of exposures and reproductive outcomes because:

1) exposed populations tend to be small in number
2) the exposure is often poorly defined
3) one is often interested in rare events such as specific malformations
4) publicity relating to the episode under study may produce or accentuate reporting bias.

In this section we discuss these problems and how they affect statistical aspects of a well-designed reproductive study: statistical power, misclassification and bias. While we concentrate on power and strategies that may assist the investigator in increasing power, many of our recommendations could be motivated from other perspectives such as the maximization of the validity and utility of the study results. Our statistical discussion is purposefully kept at an intuitive level; it certainly is no substitute for an active statistical consultant or more formal statistical texts, such as Fleiss [1]. In the discussion that follows we assume (unless otherwise stated) that the data can be represented by a fourfold table, with dichotomous end point and dichotomous exposure, in which the measure of association is usually the odds ratio.

Statistical Power

Power, defined broadly, is the ability to detect and accurately estimate changes in frequency (or in mean value). An investigator should always consider power at the onset of the study, because it may influence the strategy, and it provides him with a realistic assessment of the meaning of the results.

Power depends on:

1. The number of people likely to have been exposed, and the number of people available who are unexposed.
2. The variability of the reproductive event. For discrete events, this will depend on the usual (expected) rate of the reproductive event in the unexposed population.
3. The significance level that will be accepted as confirmation of an association, e.g., the probability that the observed change has occurred by chance is not more than 1 in 20, $p < 0.05$, or 1 in 100, $p < 0.01$. This assumes a specific probability model, and there may be more than one feasible model.
4. The magnitude of the expected effect. It is immediately obvious that if exposure multiplies the frequency of occurrence of an outcome by 10, the exposure will be easier to detect than if it multiplies it only by a factor of 2 or 3.
5. The design of the study, and the statistical techniques used for analysis.

Statistical Considerations Influencing Design

1. Selecting the end point:

The higher the frequency of an outcome in the unexposed population, the greater the power. Frequencies of selected end points are given in Table 1. The effects of variations in frequency on statistical power are discussed later, and are illustrated in Table 2.

The observed frequency of an outcome can be increased by the researcher in various ways. For instance, he can intensify case finding. Thus, if he is comparing spontaneous abortion in two communities, the more complete the ascertainment, the higher the frequency, and the greater the power (of course, the case finding must be intensified equally, in both communities).

The frequency of an outcome depends, in part, on the definition of the sample in which the outcome is measured. For instance, chromosomal and morphologic abnormalities of the conceptus are 100 times more frequent among spontaneous abortions than among livebirths. Similarly, the frequency of azoospermia is likely to be higher among couples attending an infertility clinic than among the general population.

Table 1
Frequency of Selected Reproductive End Points

Event	Frequency per 100	Unit
Azoospermia	1	Men
Birthweight*<2500 g	7	Livebirths
Failure to conceive after one year of unprotected intercourse	10-15	Couples
Spontaneous abortion 8-28 weeks of gestation	10-20	Pregnancies or Women
Chromosomal anomaly among spontaneously aborted conceptions 8-28 weeks	30-40	Spontaneous abortions
Chromosomal anomalies among amniocentesis specimens to unselected women over 35 years	2	Amniocentesis specimens
Stillbirth	2-4	Stillbirths + livebirths
Birth defects	2-3	Livebirths
Chromosomal anomalies in livebirths	0.2	Livebirths
Neural tube defects	0.01-1.00	Livebirths + stillbirths
Severe mental retardation	0.4	Children to age 15 years

* More usefully analyzed as a continuous variable, as discussed in the text of Section III.

Table 2

Frequency per 100	Sample Size of Comparison Groups	Increase in Frequency Detectable with 95% Power*
3	50	7.7-fold increase
	100	5.3-fold increase
	250	3.3-fold increase
	300	3.2-fold increase
7	50	4.6-fold increase
	100	3.4-fold increase
	250	2.3-fold increase
	300	2.3-fold increase
15	50	3.0-fold increase
	100	2.4-fold increase
	250	1.8-fold increase
	300	1.7-fold increase

* a = .10, two-tailed, or a = .05, one-tailed.

2. Sample sizes:

The number of "cases" of the "exposed" is often absolutely limited by circumstances beyond the investigator. However, sample size can be somewhat increased, even in these situations, by doubling or trebling the numbers of "controls" or "unexposed." In practice, there is seldom much benefit to increasing the comparison individuals more than threefold.

3. Significance level:

Significance levels of .01 and .05 are commonly used in experimental situations since such levels indicate that the observed results would occur rarely because of sampling fluctuations alone. In some situations, however, one might consider a false rejection of the null hypothesis in 1 out of 10 tries to be sufficiently rare than a result obtained with a = .10 would be acceptable, or at least warrant further investigation. This is not necessarily a compromise in rigor; it should be a result of comparing the undesirability of falsely rejecting the null hypothesis with that of missing an effect that is really there.

Besides the choice of the significance level for a specific test, the probability of falsely concluding that an association is present at least once is affected by the number of associations that is tested within a single analysis. Consider the situation in which the exposure is poorly understood, and anticipated effects are vaguely described as "adverse reproductive outcomes." Then the investigator, undertaking what is called "data exploration," searches for effects of an exposure on a) birthweight, b) neural tube defects, and c) congenital heart defects, and sets a 1 in 20 chance in every case of finding an effect caused by sampling fluctuations alone. Since there is a 5% chance of making this so-called "type 1 error" on every test, the cumulative probability of making at least one type 1 error can be substantially larger than 5% when multiple hypotheses are tested. For a set of k multiple hypotheses that fall together as a "family," it is possible to insure that the family-wise type 1 error rate is no larger than "a" by conducting the individual hypothesis tests at a significance level of (a/k) [2].

From the point of view of power, it is clear that adjusting the significance level for multiple hypotheses within a "family" makes it more likely that a true effect might be missed. To avoid this loss of power for specific a priori hypotheses these are usually considered to be one-element families, i.e., the significance level for that hypothesis is not adjusted for any other tests. Since it is fitting that specific a priori hypotheses be treated differently from nonspecific tests of association, the investigator should be sure to specify carefully all of the outcomes that can be anticipated at the onset of the study.

4. Magnitude of the effect:

One strategy to maximize the observed strength of an association is to control as far as possible all sources of variation in exposure or end point that are irrelevant to their association. We consider this approach: a) for the exposure; and b) for the reproductive end point.

a) Refining the history of exposure.

For reasons already alluded to, a major problem in investigations of reproduction and exposure is how to specify correctly the exposure status or exposure dose of an individual. We assume here that misclassification, or error in assigning exposure status, affects cases and controls equally. Misclassification can make a "real" association appear less, because it introduces noise, or error, into the analysis.

Statistical power will therefore be enhanced by precise data on individual exposure to reduce misclassification. When dealing with reproductive end points, precision may involve ascertaining whether exposure is maternal or paternal, the timing with regard to conception, and the route of exposure. In some situations (e.g., for workplace exposure at sites where industrial hygiene information exists) such data may be readily available. In others, at hazardous waste sites, for example, in which the composition of the fill, and the routes and timing of migration are unknown, data will need to be carefully and comprehensively developed. Thus, there is already evidence from earlier studies (Seveso, Love Canal) that the application of hypothetic exposure models, albeit sensible, has led to extensive misclassification of exposure at these sites, thus generally reducing the power of analyses to detect health effects.

Biochemical measures of exposed and unexposed individuals are to be preferred, but sound environmental and interview data regarding the residents' locations and habits relating to exposure may produce dose groupings that permit a sensitive test for effects (and may also serve as a check on response bias). It is unusual for such data to be available for Level I analysis.

In cluster situations, a plausible preliminary hypothesis as to the nature of the exposure must exist before there is any hope of invoking this strategy for increasing the power of the analysis.

Consideration of exposure in relation to the relevant parent and timing vis à vis conception may also allow analysis of a more specific hypothesis, although it should be recognized that such tests are necessarily based on smaller numbers (e.g., exposure to the mother only; exposure prior to conception only).

b) Refining the end point.

The more the reproductive event can be refined to conform with an anticipated, biologically coherent outcome, the greater the power. End points should, therefore, be limited to the items relevant to the exposure and should exclude irrelevant items. For example, if "birth defects" is the supposed untoward effect of an exposure, one may decide to exclude from the count affected offspring with single locus gene disorders born to carrier parents.

On the other hand, there may be reasons to pool malformations, thereby increasing the rate. If it is thought that the exposure acts upon more than one end point, power can be increased with this strategy. If it is thought that the exposure acts upon only one end point, power can be reduced with this strategy.

5. Statistical design and analysis:

Four examples are given below of special design and analytic techniques that may enhance power:

In these examples we are no longer restricting discussion to the fourfold table and the odds ratio.

a) Use of continuous distribution rather than discrete categories.

When the end point can be studied as a continuous distribution (like birthweight, for instance), it is usually better to analyze it in that form. Selecting one or two cutoff points and producing two or three categories is wasteful of data, and may reduce power.

b) Use of conceptions rather than women as the unit of study.

One way to enhance power when dealing with reproductive events is to use conceptions rather than women as the unit of study, since each woman may have several conceptions. However, precautions must be taken to ensure a valid statistical analysis in the presence of correlated observations. The conceptions of the same woman will have common characteristics special to that woman. Therefore, undue weight may be given to the characteristics of women with several conceptions. A spurious finding may occur if women have numerous adverse outcomes (e.g., repeat spontaneous abortion) for reasons unrelated to exposure, and these women are more numerous in the exposed population.

We may assess the extent of within-woman correlation, much as in the analysis of repeated measures, and if the extent of correlation is only slight, the investigator stands to gain much in the way of power by using conceptions as the unit in multiple pregnancy populations, with suitable control for the within-subject correlation. Such control can be obtained by statistical models allowing for sequential dependence of pregnancy outcomes.

c) Stratification, and controlling of confounding variables.

For some end points, like birthweight, several characteristics of women are known to have an important effect, e.g., prepregnant weight and cigarette smoking. These characteristics may or may not be independent of the exposure. If they are not independent, then they will need to be controlled to avoid confounding, which can lead to false inferences about the existence and magnitude of the effect. Even if they are independent, then there are situations (for instance, cohort studies) in which by controlling one may usefully remove unwanted sources of variation.

Therefore, it is prudent design and analysis strategy to subdivide the entire population into strata relevant for the purpose of controlling for confounding variables. There are, then, several methods available for combining the evidence in each stratum regarding the existence, strength, and consistency of an association across strata (e.g., the Mantel-Haenszel procedure for several fourfold tables, or Fisher's method for combining evidence from independent experiments).

While controlling for confounding variables reduces bias in the estimates, and may increase power in some cases as a result of reduction of bias, it is often the case that inclusion of additional control variables in a statistical model reduces power by decreasing the degrees of freedom available in the data. This is especially likely to be the case when the sample sizes are small (N <30) and fixed. In such situations, stratification should be limited to variables for which there are strong a priori grounds for concern with respect to confounding. This consideration is negligible with large sample sizes.

d) Clustering techniques.

On occasion clusters of events arise strictly by chance. Determining when these aggregations are meaningful or merely random is particularly difficult when the apparent excess involves a rare condition. Analysis of clusters of uncommon events requires the use of specially developed statistical methods known as clustering techniques. These methods are sensitive to low-level epidemicity, whether it occurs in time or in place, or in both time and place, and their use will permit sound conclusions as to whether or not the observed excess is random.

Comparing End Points with Respect to Power

Table 2 shows, for various sample sizes, the magnitude of the effect that can be detected at the 0.1% significance level with 95% power [3]. Three levels of frequency are considered: events occurring at rates of 3%, 7%, and 15%, respectively. (Table 1 gives examples of reproductive end points which arise at these frequencies.)

Because the size of the sample studied also contributes to the power of the test, four different sample sizes are examined in relation to each of the three levels of frequency. These numbers (50, 100, 250, 300) have been chosen as reproductive studies in a small-to-moderate sized community. There might, for instance, be about 100 couples of reproductive age in the study area who, over the period of study, collectively contribute 300 pregnancies of which about 85%, or 250, may end in livebirths. Should one wish to conduct sperm studies, one might estimate, based on typical rates of participation, that perhaps 50 males among the 100 eligible will volunteer semen for analysis.

For each of these parameters (sample size and frequencies), Table 2 indicates the variation in statistical power by citing the increase in frequency that is detectable with a high level of certainty. Thus, for example, for an event whose usual rate of occurrence is 7%, one could be 95% sure with a sample of 100 of not overlooking a three-to fourfold rise in frequency; effects smaller than this — a doubling, say — may not, however, be ruled out with the same level of assurance.

A review of Table 2 shows that the power to discern modest effects increases with increasing frequency of the event under study. For a given sample size, events with a baseline frequency of 15% provide a more sensitive test than do events with a baseline rate of 3%, or even 7%.

Further, for a given level of frequency the effect size detectable increases with increasing size of the sample studied. Thus, if one considers events with a frequency of about 3% — for example, stillbirth or birth defects — one also needs to consider the definition (hence the size) of the sample in determining the statistical power of studies of these events.

It should be noted that the computations in this Table assume that the groups being compared are equal in size — that is, 50 each of 100 each, etc. However, the use of multiple comparisons, or unequal-sized groups, can improve the statistical power of a study in which the size of one of the groups is fixed, although the increase in power is not linear with each additional subject. For purposes of estimating power, the effective sample size with unequal groups is based on the harmonic mean of the groups being compared:

$$n = \frac{2n_1n_2}{n_1 + n_2}$$

Bias

It is clear that an aware and exposed population presents difficulties to the investigator well beyond the statistical issues. In Section VI we will discuss some of the strategies which may be used to control for the problem of reporting bias. However, we consider here one issue that is statistically not easily solvable. When community reports of adverse events are the spur to subsequent health studies, statistical concerns arise that the hypothesis has been suggested by the data. Usual tests of significance may be inappropriate because one has chosen to test for an effect in an area in which an effect has already been noted. Ideally, one would test the observation in another area. However, frequently the exposure circumstances may be unique or it may be necessary for other reasons to confine investigation to the area from which the original report emanated. One needs then a satisfactory way to compensate for the positive bias without introducing bias in the other direction. If the community is small, the events noted rare, and communication such that most of the current cases have already been found, then excluding the reported cluster constitutes too severe a penalty, biasing the test to a negative finding. If exposure is continuing, one could consider a prospective investigation of what would then truly be an independent sample. But with rare events, prospective study is usually not sensible. There may be no truly satisfactory solution and one may be forced to include the original cluster in the analysis, relying on scrupulous definition of the denominator and unambiguous results to estimate the probability that the increase has occurred by chance.

SECTION IV

GUIDELINES FOR LEVEL I ACTIVITIES: ACCESSIBLE SOURCES

Introduction

We define a Level I investigation as one that avails itself of easily accessible, routine records. The purpose is to be speedy, and parsimonious. A firm positive result can lead to quick preventive action, as has happened many times in the past. An inconclusive result requires careful evaluation. Since an absolute limit on Level I activity is set by the presence of accessible data, one task fufilled by this Committee was to set out the data that do exist, and to explain their strengths and weaknesses. A later task may be to formulate recommendations for extending and improving the basis of Level I type studies. In highly developed societies, these may be our most important resource.

The availability of baseline data, and its analysis, increases the chances that clusters will be discovered. Baseline data can also provide comparative data that otherwise may not be available. Birth and death records can provide baseline information for evaluation of malformation clusters, and can also provide a current survey of malformations. Unfortunately, the congenital defect items on the birth and death record are tabulated in only a few states, and appropriate analysis is seldom performed in a timely manner.

The basic methods for Level I data collection and analysis are similar for Cluster and Exposure situations. However, end points that are examined in Cluster situations may be limited to those on which suspicion has fallen (such as birth defects or miscarriages). By contrast, in Exposure situations such as Love Canal, all adverse reproductive outcomes or as many as feasible will have to be addressed.

1. Select the end points:

A first task is to select those adverse reproductive outcomes with which we can concern ourselves in Level I. These include:

1. Spontaneous abortion (if accessible through record systems)
2. Late fetal death
3. Birth rate
4. Low birthweight and/or premature gestation
5. Congenital malformation
6. Newborn screening, especially for hypothyroidism*
7. Outcome of an alpha-fetoprotein screening program, especially for neural tube defects.

Among the adverse outcomes we monitor, low birthweight and congenital malformations are favored by public health workers as indices of adversity. Valid birthweight data are routinely available on vital records; birthweight has been shown to vary with environmental exposures, as described later. Congenital malformations, if obvious, can be monitored and are perceived as carrying heavy burdens. Once the reproductive outcomes to be evaluated have been selected, the verification and data collection can begin. During this process, change due to artifacts and biased ascertainment can be identified.

---

* The stored blood spot may also provide a valuable resource for additional analysis.

2. Define the population at risk:

The geographic area and population that is at risk must be well defined. This is essential to develop the denominator, and to determine if the reported events are unusual in frequency and/or severity. The area and population could be within a defined distance from an environmental hazard.

3. Verify the reports:

A) In certain situations in which increases are reported by hospitals, individual physicians or concerned citizens, one must be sure that there is not a "numerator epidemic." It is possible for high-risk pregnancies to be referred to one hospital or physician, and this may create a false increase.

B) Verify the diagnosis. In some situations there is overreporting of minor defects because of sudden awareness of a problem, or the introduction of a new technique, or a new physician moves into a hospital or community. Certain minor birth defects are particularly susceptible to overreporting.

C) Possible problems with the data collection or reporting system, such as birth and death certificates. There can be simple coding errors or changes in coding indices that create false epidemics.

4. Identify records:

During the data collection phase, there are several existing record systems to examine at the local, state, national, and international levels. When pursuing these investigations, identification of the available data sources is very important for case finding and for establishing a reliable data base to use for comparative purposes. The extent to which one pursues the case finding depends on the situation at hand. The following list reviews some of the available data sources, and their advantages and disadvantages.

A) Local or Community
  1) Hospital — Medical indexing system
        Obstetric logbook
        Nursery logbook
        Autopsy reports
        Discharge summaries
  2) Physicians
  3) Clinics — maternal and infant clinics
  4) Cytogenetic labs
  5) Occupational records

These data will be the most reliable and accurate but will require the most effort to collect.

B) State
  1) Vital records — Livebirth certificates
        Fetal death certificates
        Infant death certificates

Vital records are a good source for evaluating outcome such as low birthweight, infant mortality and birth rate. When looking at birth defects, one must be aware of serious underreporting of malformations on birth certificates. It is also possible that deaths may be underreported.

2) State birth defects monitoring programs. New York, Nebraska, Florida and Washington have such systems already. Several other states are planning them. Some of these are birth certificate systems only, while others combine hospital records and birth certificates.

3) Other state resources — Maternal and child health units in the health department
State Epidemiologist
Crippled Children's Service
Mental retardation centers
Various voluntary health associations (i.e., March of Dimes, Spina Bifida Association)

C) National

1) The National Center for Health Statistics (NCHS) publishes vital statistic data collected through states on numerous topics. This is an excellent source for determination of state, metropolitan, and national birth rates, infant mortality, and low birthweight. Further, the NCHS is a good source from which to obtain national rates of congenital malformations for comparison with state vital records. There are serious underreporting problems, so comparisons should be made only from vital records (birth certificates).

2) Center for Disease Control, Birth Defects Branch — Operates two birth defects surveillance systems — one national, the BDMP; and one local, the MACDP.

The national Birth Defects Monitoring Program (BDMP) monitors the incidence (about one-third of all births) of congenital malformations among 1 million newborn discharge summaries annually. This data source is not population-based and it is not a random sample of U.S. births; nevertheless, it represents the largest single source of uniformly collected and coded discharge data on birth defects in newborn infants. Although the BDMP functions primarily as an early warning system, it can be useful also for correlating incidence patterns, with such trends as temporal and geographic distribution of drugs, chemicals and other possible human teratogens. The BDMP is an excellent reference for regional and U.S. birth defect incidence rates among newborns from hospitals. The problem with hospital records on newborns is some underreporting of defects, since many are not diagnosed until later in life.

The Metropolitan Atlanta Congenital Defects Program (MACDP) is an intensive surveillance system using several methods to identify infants born with birth defects in the Atlanta area. Cases included in the system are all infants with abnormalities diagnosed before 1 year of age, whose mothers resided in the 5-county

Table 3
Characteristics of Two Congenital Malformation Surveillance Systems

Characteristic	MACDP	BDMP
Population	Five-county metropolitan Atlanta area. Population based on 24,000 births/year.	1200 hospitals throughout U.S. 1 million births/year.
Rapidity of reporting	Depends on defect — usually 2 months delay.	3-6 months.
Nosology	ICD-8 modified.	H-ICDA and ICD-9-CM.
Methods of ascertainment	Chart review at obstetric and pediatric referral hospitals. Cytogenetic laboratories. Vital records.	Cover sheet of neonatal discharge summary.
Identification of syndromes of associated malformations	Good. Published in surveillance report.	Poor.
Follow-up studies	Yes. Regular interviews.	Difficult. No regular interview.
Linkage of maternal and infant records	Yes.	No.
Data analysis	Baseline period: 1968 to 16 months before current period. 169 defect categories. Separate analysis for whites, blacks, and all races combined. Data analyzed each month.	Baseline period: 1970-1973. 161 defect categories. Races grouped for routine analysis. Data analyzed every 3 months.

metro-Atlanta area. The MACDP has been in operation since 1968 and is an excellent source of birth defect incidence data for comparative purposes.

Data from the two systems are published quarterly in the Congenital Malformations Surveillance Report. The characteristics of the two CDC congenital malformation surveillance programs are outlined in Table 3.

D) International

Several countries have established malformation surveillance systems. Informally, 10 of these countries share birth defect data through the International Clearinghouse for Birth Defects Monitoring.

SUMMARY

Having selected the end points, identified the population at risk, confirmed the reports of adverse outcome, and compared the rates established thereby with expectations based on existing records, the investigator may assess whether the residents in the study areas have experienced excessive adverse outcomes. He then must decide whether to proceed to Level II activities. As noted above, given a significant excess, it may be useful to pursue the investigation further. Given an inconclusive result, the decision as to whether or not to proceed will be influenced by many considerations, not all of them scientific.

SECTION V.

DECISION MAKING: MOVING FROM LEVEL I TO LEVEL II

Level I studies are limited by definition to easily accessible end points. They will lack power because they will usually be limited to poorly defined measures of exposure (for instance, to global measures for communities, as opposed to individual measures). They may also be deficient by being unable to take into account other known factors for reproductive outcomes, thereby risking confounding.

For a wide range of end points known to be sensitive to environmental exposure (spontaneous abortion; sperm abnormalities; somatic cell damage), Level I studies cannot be carried out. These end points require more time, more funds and more community involvement. We must consider the basis on which a decision might be made to include such end points and to pursue more in-depth investigations.

General Considerations

There are several steps to be considered within Level I evaluations, whether the situation is a Cluster, an Exposure, or, as is often the case, a combination of the two. The first tier of concern for evaluation of a Cluster is limited to consideration of the original observation(s). This might be followed by additional case findings through review of one or more readily accessible existing record systems. The period of observation for adverse outcomes might be expanded backward or forward in time to gain greater confidence in the legitimacy of the observations. Additional related outcomes might be considered in tandem. At this point it may be appropriate to obtain by interview additional descriptive information from members of the clusters to learn about possible exposures, firm up the time frame in which the events occurred, and generate etiologic hypotheses.

Initial observations on exposure situations may be limited to the knowledge that someone lives near a presumed hazardous site. Generally, more detailed data are necessary before proceeding, such as ambient environmental data or, better yet, measurements of specific compounds in homes or industrial settings. Samples of body fluids or tissues indicative of significant human exposure may be compelling evidence to continue or expand an evaluation.

In the end, the decision to proceed from the Level I descriptive evaluation to Level II analytic studies involves several factors. The first and perhaps most important of these considerations is, or should be, the *biologic meaning* of the descriptive data thus acquired. Is an association *plausible?* Is the level of human exposure high? Is the exposure in question to a highly toxic compound or agent? Second, statistical considerations are also important. Level I data for clusters should at least suggest an *increase of observed over expected* events. The number of cases or potential cases and/or the number of exposed or potentially exposed individuals should be large enough to be evaluated. Finally, the level of public concern has to be added to the equation. It should be noted that the final decision to proceed with additional studies is generally not a unilateral action but rather a joint move of local, state, and/or federal officials and ideally should proceed in a *timely fashion.* Level II studies will often require contact with individual subjects. In addition to satisfying the right of a community to be informed of the *possible* presence of an Exposure or Cluster, explaining the need for Level II studies to the community in advance may well alleviate the anxiety that might be generated when the Level II study actually begins, and individual participation is solicited.

Prior notification may also facilitate obtaining consent from both "cases" and "controls." Standard procedures should be elaborated for obtaining permission from both of these groups for release of their names to the investigators conducting Level II studies, and for assuring that participants will be informed of the results.

Summary of Criteria for Moving From Level I to Level II

1. A statistically significant association is observed at Level I, but there is a need to explore a broader spectrum of outcomes, and/or to specify more precisely the relationship of the outcomes to the exposure, e.g., threshold and dose-response components of the exposure.
2. The end point that stimulated the investigation, or that seems most biologically coherent with the exposure, is not accessible to Level I studies.
3. The results in Level I are inconclusive: the trend is in the expected direction, but the investigation lacks power (e.g., a sixfold effect can be shown to be unlikely, but a threefold effect is compatible with the findings). This is the most difficult situation, but perhaps the most likely.

SECTION VI

GUIDELINES FOR LEVEL II INVESTIGATIONS: EPIDEMIOLOGIC STRATEGIES

Failing a clear-cut result (either negative or positive) between exposure and Level I outcomes, the investigator may move on to further epidemiologic studies to examine an association studied in Level I in more detail, or to examine other end points. The statistical considerations of power and bias discussed in Section III now find application in the choice of study design, enabling the researcher to make maximal use of small numbers, rare events, and uncertain information sources. This will be true, whether the end point of interest is one of those listed in Section II or one described under somatic cell changes. Case-control and cohort designs each have advantages and disadvantages depending on the circumstances; in both, errors in planning and oversight in execution may reduce the power of the test or introduce bias. Experience is the best master. In this Section, principles of design are illustrated by examples from the field of reproduction, drawing attention to any special strengths or difficulties that have faced investigators.

Whether the provocation to an inquiry is based on a Cluster situation (originating in a reported excess of adverse outcomes) or an Exposure situation (originating in some supposedly hazardous exposure) does not usually influence the strategy chosen to study the relation between an exposure and reproductive functioning. One distinction (discussed in Section III) is the reported observation of an apparent increase in the frequency of a particular outcome, in the Cluster situation. A report of this kind cannot be ignored and the particular outcome noted must reasonably be included among the effects studied. One way to avoid the bias inevitably introduced is to extend the search to include other outcomes not yet noted, but reasonably expected to be associated with the reported outcome; i.e., if anencephaly is reported, investigate spina bifida; if prematurity is reported, investigate late fetal deaths. Also, since there are several examples of exposures which relate to more than one reproductive outcome (e.g., the associations of smoking with both decreased birthweight and increased fetal death, and of alcohol drinking with fetal death, decreased birthweight and congenital malformation), a comprehensive evaluation of the reproductive effects of an exposure will usually include study of a range of reproductive end points.

Two approaches may be taken in Level II (or III) studies:

In the *case-control study,* the frequency of exposure among persons who experience the disease (cases) is compared with the frequency of exposure among persons who do not experience the disease (controls).

In the *cohort study,* the frequency of disease among exposed persons is compared with the frequency of disease among unexposed persons. In a retrospective cohort study both exposure and disease have occurred before the study begins; in a prospective cohort study, the investigator follows the exposed and unexposed cohorts in order to ascertain outcomes. These approaches differ in the starting point for the definition of the sample. In the case-control study, the sample is defined by the outcome under study; whereas in the cohort study, the sample is defined by exposure status.

In the first two segments below, we consider some of the issues in design, analysis, and interpretation that are special to each of these research strategies, emphasizing those relevant to reproduction. In the third segment, we consider issues that are generally applicable to the study of the relation between an exposure and adverse reproductive functioning, regardless of the research strategy employed to examine the question.

1. Definition of the Control or Unexposed Group

a) The case-control study: In the case-control study the frequency of exposure among persons experiencing the disease (cases) is compared with that among persons not experiencing the disease (controls). By definition the control group is free of the outcome under study. Controls and cases should ideally be comparable in the following characteristics: 1) the a priori probability of exposure; that is, they should be drawn from the same population; 2) in the method of ascertainment; 3) in the method of data collection on exposure status and potentially confounding variables, and the reliability and validity of these data; and 4) in all characteristics (other than those being studied) which relate both to the outcome under study and to the exposure variable.

In practice, it is not always known at the outset of a study whether cases and controls are likely to differ in characteristics which relate both to the outcome and the exposure. Thus, in design of the study, efforts are made to ensure that cases and controls are comparable in all known risk factors for the disease. The ascertainment of cases and controls from the same population may be sufficient to ensure such comparability; in other instances, cases and controls may be matched for one or several characteristics which relate strongly to the outcome under study, and which may be associated also with exposure status. Table 4 lists, for several reproductive outcomes, the most strongly associated risk factors.

Table 4

Outcome	Significant Risk Factors
Spontaneous abortion	Maternal age Maternal smoking Maternal alcohol drinking Prior spontaneous abortions
Stillbirth	Maternal age Maternal smoking
Birthweight	Maternal age (young) Maternal parity Maternal ethnicity Maternal smoking Social class
Neural tube defects	Parental ethnicity (Irish vs non-Irish) Maternal age Social class (in some geographic areas) Prior neural tube birth
Down syndrome	Maternal age
Cleft lip and/or palate	Prior birth with cleft lip and/or palate
Trisomy (among abortions or term births)	Maternal age

More than one type of control may satisfy the criteria listed above. For example, if cases are the parents of infants with neural tube defects, the following control groups might be considered: parents of stillbirths; parents of livebirths with another type of congenital defect; and parents of normal liveborn children. The first two control groups in this example have the advantage that all parents have suffered an adverse reproductive outcome. Thus, if interview data are to serve as the primary source of information on exposure status, all parents may be equally accurate or inaccurate in their reports. They pose the disadvantage, however, that if exposure is related to more than one outcome, an association may be missed. The parents of normal children present converse advantages and disadvantages; that is, they allow the possibility of different accuracy in recall, but the certainty that the group is indeed unaffected without any adverse outcome. Often the solution to this dilemma in choice of controls is to select two control groups; one defined by an adverse outcome other than that being studied, and the other unaffected by any adverse outcome.

b) The cohort study: In the cohort study, the frequency of adverse outcome is compared between exposed and unexposed individuals. The study may be conducted retrospectively or prospectively with respect to outcome. Two approaches may be taken to define the unexposed group.

First, the unexposed group may have no exposure to the agent under study (e.g., comparison of individuals in an exposed community with individuals in an unexposed community).

Alternatively, the unexposed group may be exposed at lower doses than the exposed group (e.g., workers with varying levels of exposure to the same agent; individuals living at varying distances from the site of environmental contamination). In this instance, an effect may be missed if both low and higher doses of exposure are associated with the same effect.

The exposed and unexposed cohorts should be identical insofar as possible in:

1. The method of identification of the cohorts;
2. The method of follow-up;
3. The method of data collection on the outcome variables and control variables; and
4. Known risk factors for the outcomes under study.

The third criterion listed above puts some restrictions on the use of population data on the frequency of adverse outcomes as data of the 'unexposed' group. This approach can only be entertained if the methods of follow-up and data collection in the unexposed population were identical to those used for the exposed group, and if the unexposed population is comparable in all risk factors known to influence the outcome.

2. Case-Control and Cohort Studies Compared

a) Number of cases required: For a given effect size, level of significance and power, the case-control design will require fewer individuals than the cohort study, when the outcome being studied is rarer than the exposure.

When the exposure is rarer than the outcome, the cohort design for a given effect size, level of significance and power will require fewer individuals.

b) Number of controls and number of exposed: It is possible to increase power (for a given significance level and effect size) if two or three controls are chosen in a case-control design. Similarly, power can be enhanced by doubling or trebling the size of the unexposed in a cohort study.

c) Bias in recall: In case-control studies, this refers to the tendency for persons who have experienced an adverse outcome, or who have been made aware of a likely relationship, to recall an exposure selectively. In a retrospective cohort study, this refers to the possibility that the exposure status influences the ascertainment of outcome. For instance, this could occur if the source of data on adverse outcomes were through interviews with exposed and unexposed cohorts, rather than through prospective follow-up and ascertainment by the investigator. In retrospective cohort studies in which data on outcomes are obtained from medical records, consideration must be given to the possibility that exposure status may influence medical service use.

d) Estimate of risk: The measure of an association in cohort studies is the relative risk, while from case-control studies it is the odds ratio.

e) Time and cost: Prospective cohort studies require following a group over a period of time, hence they risk systematic attrition. To some extent this can be overcome with intensive efforts at maintaining cohort size, which may prove costly in the end. Some attrition may be inevitable, however. Case-control and retrospective cohort studies may involve about the same amount of time and expense.

f) Clinical description: Case-control studies may permit a fuller clinical investigation of the "case" (hence, more precise clinical classification). Prospective cohort studies may permit more precise measure of the exposure.

g) Spectrum of outcomes: Case-control studies typically explore one outcome. Therefore, if another outcome is the more usual effect of the exposure, it will be missed. Of course, several case-control studies, each of a different end point, may be carried out simultaneously. Cohort studies often permit a fuller appreciation of a spectrum of clinical outcomes. By contrast, case-control studies permit study of a fuller spectrum of exposures. However, this may be less of an advantage in the situations under consideration here.

3. Issues Specific to the Study of Reproductive Effects

In this section, we consider issues specific to the study of reproductive effects, regardless of whether a case-control or cohort study is undertaken.

a) The exposed parent and the time of exposure: The study of the relationship between exposure and human reproductive outcome is unique, since exposures to the mother, father, or both may influence reproductive success. Furthermore, these exposures may have occurred long in the past, immediately prior to conception, or during gestation. Even in this latter instance, exposures to the father may be relevant since some agents are carried in the semen and may be transmitted to the developing fetus via intercourse; and other agents may be carried home on work clothes and thus result in maternal (and fetal) exposure.

For some adverse outcomes, it is possible to limit the relevant period of exposure. Thus, nearly all chromosomal anomalies (excluding mosaicism and tetraploidy) must arise in a germ cell of either parent prior to conception or at fertilization. Exposures that occur during pregnancy are not relevant to the genesis of chromosomal anomalies. Similarly, decreased birthweight, unassociated with any other malformation or disability, is likely to result from exposures that occurred during gestation. For congenital malformations, the embryology of the defect will determine a time period after which an exposure could not have been causal.

b) Recall bias in assessment of exposure: This is the most serious disadvantage of a case-control study. Recall bias, which implies that the data on exposure may be influenced by the occurrence of the adverse outcome, must be suspected whenever interview data from affected and unaffected individuals serve as the only or primary source of information on exposure status. Recall bias may produce either spuriously positive findings (i.e., cases overreport exposure, controls underreport exposure, or both) or spuriously negative findings (i.e., cases underreport exposure). There are several ways in which the effects of recall bias may be assessed: 1) by comparison of self-reports of exposure with records of exposure collected prior to, or independently of, the outcome; 2) by biochemical measurement of exposure to the individual (e.g., plutonium, lead); and 3) by comparison of the frequency of self-reported exposure among several "worried" groups thought to have etiologically distinct conditions (e.g., chromosomally normal and chromosomally abnormal spontaneous abortions, neural tube defects and Down syndrome) with that among controls.

c) Source of data on outcome: Earlier we discussed the value of vital certificate data and medical records in identification of adverse reproductive outcomes. Another source of data in reproductive studies is interview data obtained from the parents. For outcomes such as birthweight and sex of the child, vital certificate data provide a source for validation. For outcomes such as congenital malformations, perinatal deaths and spontaneous abortions, hospital and physician records may be used for validation. However, since a large proportion of women may not seek medical attention for care of a spontaneous abortion, interview data will usually include spontaneous abortion data that cannot be validated from another data source. Since reporting of outcomes may vary with exposure status, the most prudent analytic approach to data of this type is to analyze the information on validated and unvalidated events separately. These analyses should be carried out controlling for gestation at abortion, since the majority of abortions for which care was not sought will have occurred in the 1st trimester of pregnancy. Insofar as these analyses within gestational groups (e.g., 8-12 weeks, 13-16 weeks, 17-28 weeks) show the same association, these data could then be combined.

If the identification of adverse outcomes is to depend on hospital records, physician charts, and vital certificates, then care must be taken to understand the medical facility use patterns of the population being studied. Information on birth certificates will provide some sense of these patterns; interviews with physicians, hospital administrators, and members of the community or workplace will provide additional information.

d) Can the unexposed sample be drawn from published data? In general, published series describing the frequency of reproductive outcomes among populations other than that under study will provide only "ballpark" estimates for the expected frequencies of events. Since, for the most part, these studies will not derive from the same population as the exposed sample, it is unlikely that they will substitute for the "unexposed" group in this second stage of an examination between exposure and reproductive outcome.

e) Control of potentially confounding variables: Nearly all of the known risk factors for pregnancy outcomes involve maternal exposures and characteristics (Table 4). In studies in which the effects of male exposure are being examined, the data on maternal characteristics and exposures will still need to be collected. Similarly, when the dependent variable is a characteristic of the sperm and semen, male characteristics and exposures are relevant.

SECTION VII

LEVEL III: LONG-TERM FOLLOW-UP STUDIES

With few exceptions, this type of design has been considered mainly for the purpose of discovering environmental carcinogens. The prospective studies of Hiroshima and Nagasaki, which are an important exception, examined reproductive outcome in the offspring of survivors.

In theory, one could create a list of individuals supposedly exposed to some adverse substance, and follow them till death. Such an approach could also be used to determine whether those individuals with a raised incidence of somatic cell changes are at increased risk for reproductive problems or cancer.

Such studies would be greatly facilitated by the existence of centralized and accessible registries of births, deaths and diseases, such as cancer, or of chromosomal anomalies, and by the development of automated procedures for record linkage and follow-up. Such systems are already being developed in

Canada and the United Kingdom, and include occupational information. Such automated follow-up procedures must have built-in safeguards so that confidentiality of health records and personal privacy are not compromised. In the U.S., the National Death Index is scheduled to begin functioning in 1981 [4]. The Index, to be created by the National Center for Health Statistics (NCHS), will enable those engaged in prospective studies to discover if an individual has died; and if he has, within which state. The next step, to discover cause of death for instance, would still be made at the state level but the Index is nevertheless an important advance on current possibilities for prospective studies. The NCHS is also planning a new data base on occupational mortality, and to this end a sample of states will begin the coding of the deceased's occupation, information which has long been part of the standard U.S. certificate, but usually not coded by state vital registrars. Census Forms which ask for detailed information on life-style and occupation are also proposed.

In order to permit follow-up studies using such records, sufficient information on exposed or control individuals must be kept to allow unambiguous identification of relevant vital and health records, including death registrations, and registries of cancer and genetic disease. Such information might include name, date of birth, names of parents, hospital record number, and other identifying information.

SECTION VIII

DATA ON SELECTED END POINTS

A. STUDIES OF SPERM*

1. Background

Studies of chemically exposed domestic animals, rodents, and humans have shown that sperm anomalies can be used as indicators and, in certain cases, dosimeters of induced antispermatogenic effects (for review see [5]). Since sperm are easy cells to obtain in large numbers and represent spermatotoxic as well as possible genetic damage to the gonads, sperm assays have received much attention in the assessment of reproductive damage and mutagenicity.

A recent survey of the literature [6,7] showed that human sperm assays have been more widely used than was generally suspected — more than 100 papers were found on the use of semen assays in assessing spermatogenic function in chemically exposed men. Studies cover 43 single agents, 11 complex mixtures, and 17 sets of multiple agents. About 85% of the exposures were to experimental or therapeutic drugs, about 10% were to occupational or environmental exposures, and about 5% involved personal drug use. Of the 71 chemical exposures studied, 48 were found to have some effect on human sperm production. See Table 5 for examples of the single agents studied. Studies of complex mixtures (e.g., occupational exposure to DBCP, personal use of tobacco, etc.) and combinations of 2 or more single agents were not included in this table.

---

* Work performed under the auspices of the U.S. Dept. of Energy by the Lawrence Livermore National Laboratory under contract no. W-7405-ENG-48.

The mechanisms underlying induced human sperm anomalies are poorly understood. An evaluation of the results with sperm morphology assay in mice suggests that sperm morphology may have some value in identifying carcinogens and germ cell mutagens [6]. Data from human sperm studies are very limited, and at present, the main information that can be gained from the use of human assays is whether human spermatogenesis is affected by exposure to a chemical agent or mixture.

Table 5

Single Agents Studied with Human Sperm Assays[*]

Positive Effects	Suggestive but Inconclusive Effects
Acridinyl anisidide	Centchroman
Adriamycin	Colchicine
Aspartic acid	Diethylstilbestrol
Chlorambucil	Fluoxymesterone
Chlomiphene	Methadone
Cyclophosphamide	Metronidazol
Cyproterone acetate	Nitrofurantoin
Enovid	Trimeprimine
Gossypol	
6 Medroxyprogesterone	
Metandienone	
Methotrexate	
Nilevar	
Norethandrolone	
Norethindrone	
Prednisone	
Progesterone	
Salicylazosulfapyridine	
Testosterone	
Testosterone cyclopentylpropionate	
Testosterone enanthate	
Testosterone propionate	
WIN 13099[**]	
WIN 17416	
WIN 18446	

[*] Includes studies on sperm counts, motility, morphology, and YFF. The assignment of individual agents into columns is based on the data provided in the papers reviewed by the Gene-Tox Panel and may change as more data become available. Does not include studies of single agents showing no effect.

[**] See reference [7] for details of the "WIN" compounds.

2. Parameters to be Studied

Four human sperm parameters can be studied — count (density), motility, morphology (cytology), and YFF (a new test thought to represent Y-chromosomal nondisjunction during human spermatogenesis).

Sperm count is reported as the number of sperm per ml of ejaculate (or total sperm ejaculated) and is usually determined by hemocytometer. The measurement is technically easy and automated methods are also available. However, interpretation of results may be confounded by a number of factors such as variable continence time before obtaining specimen, and collection of incomplete ejaculate. For normal ranges see review by James [8].

Sperm motility is the swimming ability of the sperm, and is expressed as a percentage of motile sperm, on a graduated scale of 1 to 4, or as a combination of both. Although motility may be the best true performance evaluation of testicular function in relation to fertility, it is also the most subjective parameter of the four, and is very sensitive to time and temperature after collection. Thus, semen motility is a very difficult parameter to measure in a large-scale cross-sectional study, especially when samples are collected at home. Normal ranges of sperm motility have been difficult to define and are usually laboratory- and scorer-specific [9].

Sperm morphology (also referred to as seminal cytology) is the visual assessment of the shapes of sperm in an ejaculate. Although sperm-head shape is usually emphasized, some assessments also incorporate midpiece and tail abnormalities. In general, there has been little agreement in the definition of normal shapes or in the categories of abnormal shapes. This has resulted in much interlaboratory and interscorer variability [10,11]. Several studies [12-14] have shown that quantitative approaches to the visual assessment of morphology can be used with considerable success. The morphology assay is usually performed by using air-dried smears, fixed, and stained with a modified Papanicolaou method [15]. Classification of sperm into shape categories can be done systematically. The criteria for morphologic analyses must be carefully controlled and slides of concurrent controls should be analyzed together with slides of exposed men in a blind-study design. One approach to assuring a uniform scoring criteria for morphology is to make repeated comparisons to a coded set of standard slides at regular intervals throughout the analyses [7]. Using this latter method, normal ranges have been established for several unexposed populations.

The *YFF* test is based on scoring the frequency of fluorescent spots in human sperm stained with quinacrine dye. Based on studies in somatic cells, it is thought that these spots represent Y chromosomes. Although one expects approximately 50% of the sperm to have one spot, in practice frequencies are in the 30-40% range. The YFF test scores the frequency of sperm with 2 spots, which are thought to represent sperm with 2 Y chromosomes due to meiotic nondisjunction. Unlike the other sperm assays (counts, motility, and morphology), YFF has no counterpart in common laboratory or domestic animals. The Y-chromosomal fluorescence seems to be unique to man and the gorilla.

For the analyses of sperm with double fluorescent bodies, air-dried smears can be fixed and stained with quinacrine dihydrochloride as described by Kapp and Jacobson [16]. It is recommended that 2,000 sperm be scored under a fluorescent microscope as OF (sperm containing no fluorescent body and presumably those with no Y chromosome), IF (those sperm presumably with one Y chromosome) and 2F (sperm presumably containing 2 Y chromosomes). Smears should be of the quality required to easily visualize approximately 50% of the sperm with a single fluorescent body.

The YFF test is very new and only a few populations of exposed men have been analyzed. Normal ranges have been tentatively described [16,17].

3. When are Sperm Studies Indicated?

The following data are very important in making any decision on whether the use of human sperm studies is warranted:

a) What are the demographics of the exposure (size of the exposed population, geographic location, etc.)?
b) Who was exposed (predominantly men, predominantly women, or both); what were the age groups predominantly exposed?
c) What are the details of the exposure (route, duration, and when did it occur in relation to the proposed time of semen collection, etc.)?
d) What are the estimates on the exposure dose (can the exposed population be divided into dose groups)?

Sperm studies in man may be warranted if there are:

a) Sufficient animal data available indicating an effect of the exposure on spermatogenesis.
b) Data that suggest there may be a problem with human infertility or pregnancy outcome that could be linked to the male.

A screening questionnaire may be used to determine if the fertility of the exposed couples is affected. This may be followed by a more detailed questionnaire to confirm this observation and to determine to what extent the infertility may be male or female related. If indicated, sperm studies may then be done to determine whether human spermatogenesis is affected and what the cause might be. This could be done as a cohort or case-control study. A systematic, statistically rigorous approach for selection of participants would have to be developed.

4. Problems in the Application of Sperm Studies

The four human sperm assays described above are technically straightforward methods. The assays for counts, morphology, and YFF are parameters that do not appear to be affected by postejaculation technical factors. Motility, however, is highly sensitive to time and temperature factors. In studies where home collection is used the motility assay is not practical.

In Table 6, the variation of the sperm assays for counts, morphology, and YFF bodies are compared. Of the three assays, the morphology assay requires the smallest sample size to detect with confidence a 25% change in the mean compared to control values. However, it is important to recognize that an exposure may affect one of these parameters and not the others. Data are still insufficient to predict a) which assay would be most sensitive to an agent, and b) the interdependence of these end points. The conservative approach for assessing changes in human spermatogenic function should include assays for sperm count, morphology, YFF, and, whenever practical, motility.

The number of men exposed to the agent as well as the likelihood of high exposures are important for study design. Since between-male variability in semen characteristics is high even among fertile and presumably healthy men, rather large numbers of cooperative subjects are required to establish differences between control and exposed groups in cross-sectional studies in which each individual is usually sampled only once (see Table 6).

Longitudinal study designs may be more appropriate when fewer men are available for sampling. In this study design, repeated semen samples from a man are collected at different times in relation to the time of exposure to assess chemically induced sperm defects. Since variation of sperm morphology within an individual is considerably less than variation among individuals [12], in principle, fewer people are required to detect induced changes. These studies, however, have several major constraints: a) repeated samplings during a period of months and perhaps years are required; b) samples before exposure are needed, (or within days of an acute exposure, which is probably insufficient time for any induced effects on morphology likely to be seen); and c) the number of men needed for an effective study is unknown.

The effects of age, smoking, illness, medication, and other possibly confounding factors must be considered in the analysis of all human sperm data.

Table 6

The Relative Statistical Sensitivities of Three Assays of Human Sperm [17]

	Counts	**Morphology**	**2 F Bodies**
Assumed Distribution	Log-normal	Normal	Normal[a]
Mean[b]	132×10^6/ml	41.9%	0.8%
Std. Dev.	160×10^6/ml	12.4%	0.7%
25% change in mean (Std. Dev. Units)	0.2	0.8	0.3
Sample size for 5% level test with 80% power	214	26	41

[a] With square-root transformation.

[b] Based on 35 unexposed, new hirees in a pesticide plant.

B. FERTILITY

There is evidence of environmental exposures that cause short-term or long-term infertility, affecting both men and women.

The number of livebirths to supposedly exposed individuals is a relatively crude way to discover the relevant process. Nevertheless, in the case of DBCP-exposed men, the dysfunction was apparent in time to the workers and their families, and it was their own reports that initiated investigations.

Several attempts have been made to use measures of fertility in surveillance:

1. A life-table technique for workers in different industries keeping information on all pregnancies as they occur.

2. A standardized fertility index, that derives an expected number of births for each worker from the National Fertility Survey. Each worker fills out a three-minute form, which covers limited demographic and reproductive information; and from that source, the number of live children that are expected to have been fathered by him are calculated. If this were done for men and women in a whole factory or industry, then a deficit, if large enough, could be demonstrated.

3. Another measure of fertility is to compare the duration of time that elapses between the initiation of 'unprotected' intercourse and livebirths. This type of measure requires more detailed interviews (Level II studies) compared to the above, but it does provide useful information. Case-control studies of miscarriages and births can certainly be used to study this end point further.

To our knowledge, infertility clinics have not yet been used for epidemiologic purposes.

We have no equivalent for women of the sperm studies now being used in men. Ovulation and menstrual cycles might be studied, in this context, but so far have received rather little attention.

C. SPONTANEOUS ABORTION

A full evaluation of the relation of a particular agent to reproduction must consider the consequences of exposure to either parent, the timing of exposure, the dose and duration of exposure, and a broad range of possible outcomes. It is unlikely that any one study can be designed to evaluate all of these hypothetic pathways, and all of these effects. However, studies of spontaneous abortions offer the possibility of examining a range of outcomes including: frequency of fetal loss overall, chromosomal abnormality, morphologic malformations, and fetal death for apparently normal conceptions.

In this section we discuss:

1. The frequency and nature of spontaneous abortion.
2. The utility of studies of the aborted conceptus.
3. Advantages in studying chromosomal and morphologic anomalies among abortions, rather than livebirths.
4. Special considerations in studies of spontaneous abortions.

1. The Frequency and Nature of Spontaneous Abortion

Approximately 15% of recognized pregnancies end in spontaneous abortion by 28 weeks gestation. Estimates from interview studies and hospital-based studies range from 10-20%; estimates from prospective studies are on the order of 20-25%. The probability of spontaneous abortion is highest in early gestation, gradually decreasing with increasing gestation. The frequency of spontaneous abortion is increased among older women (aged 30 years or more), among women with previous spontaneous abortions, and among women who smoke or drink alcohol during pregnancy. Thus, comparison of rates of spontaneous abortion for different populations should consider whether variations in these known risk factors are likely to confound the analysis and interpretation.

Approximately one-third of spontaneous abortions occurring between 8-28 weeks gestation are chromosomally abnormal. Many of the anomalies found among spontaneous abortions rarely or never survive to term; others (trisomy 13, 18 and 21) occur both among abortions and term births, but in far greater frequency among abortuses. Chromosomal anomalies are at least 60-fold more common among spontaneous abortions than term births (Table 7).

Table 7

Incidence (per 1000) of Selected Chromosomal Anomalies in Induced Abortions, Spontaneous Abortions, and Livebirths

Anomaly	Induced Abortions (from ref. [20])	Spontaneous Abortions (ref. [21])	Livebirths (ref. [22])
Sex Chromosome			
45X	8.00	43.42	0.05
47XXX	6.00	0.00	0.52
47XXY	4.00	4.20	0.46
47XYY	2.00	0.00	0.46
All Trisomies	16.00	156.85	1.27
Trisomy 13	not banded	9.80	0.05
Trisomy 18	2.00	7.00	0.12
Trisomy 21	not banded	7.00	1.25
Trisomy 16	2.00	61.62	0.00
Triploid	2.00	50.42	0
Tetraploid	2.00	14.01	0
Rearrangements	0.00	12.61	2.37
Other	24.00	40.62	.30
All abnormal	68.00	322.13	6.20
Number studied	500	714	56,952

About two-thirds of spontaneously aborted conceptions are chromosomally normal. About half of these chromosomally normal abortions are morphologically abnormal; in the majority of such cases, the dysmorphology suggests that embryonic development has been disrupted early in gestation. In the remainder of dysmorphic cases, an embryo or fetus with an anatomic malformation is found.

Some of these anomalies (e.g., neural tube defects, cleft lip and/or palate, ventricular septal defect) are similar to those found among term births; others have been described only among spontaneously aborted conceptuses.

In the remaining one-quarter of spontaneous abortions, an apparently normal embryo or fetus is identified.

An increase in the frequency of spontaneous abortion might reflect an increase in one or several of these different outcomes. Studies of the abortus, when feasible, may elucidate which outcome has been affected. In the absence of these studies, gestation may serve as a crude indicator of the likely effect. The frequency of chromosomal anomalies among spontaneous abortions decreases with increasing gestation. Among abortions less than 16 weeks gestation, at least 50% of aborted conceptions are chromosomally abnormal; among abortions of 16 weeks gestation or later, the frequency of chromosomal anomaly is approximately 25%. Thus, an exposure leading to an increase in late abortions only is most likely to have led to an increased risk of fetal death for chromosomally normal abortions. The converse statement cannot be made so easily for early abortions, since an excess might represent either increased aneuploidy or an increased rate of fetal death for euploid conceptions.

2. The Utility of Studies of the Conceptus

Cytogenetic and morphologic studies of the conceptus will, of course, help to elucidate the mechanism which accounts for an association of an exposure with spontaneous abortion. These studies can aid also in distinguishing the relevant definition of exposure, with respect both to time of exposure and parent exposed. For nearly all chromosomal anomalies the error must occur either prior to conception, in the germ cells of either parent, or at the time of fertilization. Thus, knowledge that the conceptus is abnormal chromosomally will usually limit the search for causal factors to those exposures which occurred in either parent prior to conception. For some anomalies (i.e., tetraploidy, mosaicism), the search is directed to exposures occurring at the time of fertilization or shortly thereafter. In some trisomies and most triploidies, it is possible to distinguish the parent in whom the cytogenetic error originated; in such cases, the search for antecedent factors can be narrowed down to that one parent.

The processes underlying the abortion of chromosomally normal conceptions can be illuminated by consideration of the morphology of the abortus. For instance, in about half of these cases, the aborted specimen consists of only fragments of membrane, yielding little information on the stage of intrauterine life when development stopped. A similar proportion of specimens consists of an empty sac, sometimes with a small portion of cord. The early cessation of development which is evinced here may be due either to factors operating prior to or at the time of conception (associated possibly with genetic mutations which are, as yet, not able to be measured) or to factors operating early in gestation.

The epidemiology of this type of abortion is virtually unexplored.

In the remaining 50% of abortuses, an embryo can be identified. These embryos are of at least three types: disorganized embryos, apparently normal embryos, and embryos with focal malformations. In the first type of embryo, development has been disrupted early in gestation; causal factors most likely lie in exposure(s) occurring either prior to conception or early in gestation. In the second type, the embryos are apparently normal, although they vary in size, sex, gestation, and in degree of maceration. Each of these dimensions may provide clues as to the process underlying the abortion. The abortion of such an embryo or fetus raises the possibility that a maternal factor, including the wide range of common or unusual substances to which the mother is exposed and which cross the placental barrier, has interfered with the maintenance of pregnancy. In the third type, that is, an embryo or fetus with a focal malformation but normal karyotype, teratogenesis may again have its source in the fetal environment provided by the mother.

3. Advantages in Studying Chromosomal and Morphologic Anomalies Among Abortions Rather than Livebirths

a) Statistical power

The majority of chromosomally abnormal conceptions (at least 92%) are lost through spontaneous abortion rather than surviving to term. It appears also that a large proportion of fetuses with focal malformation are lost through spontaneous abortion, although this frequency is not as well documented as that for chromosomal anomalies. Since the frequency of these anomalies is considerably higher among abortions than among livebirths, changes in either the type or frequency of abnormality may be missed in studies of defects at term, unless the exposed population is very large, or the defect unique and rare (e.g., thalidomide and phocomelia). There is statistical power to detect smaller effects when the relationship of exposure to defect is studied in abortions rather than births. Furthermore, there is economy in the numbers of pregnancies which must be examined. For example, in order to identify an exposure which doubles the incidence of chromosomal defect at conception, the records of 22,843 exposed newborns would have to be examined to insure an 80% chance of detecting the effect. In contrast, to detect the rise in the incidence of spontaneous abortion which would follow on this same increase in the frequency of chromosomally abnormal conceptions, only 901 exposed pregnant women need to be identified. An even more powerful test would be to search for an increase in chromosomal anomaly within a population of spontaneous abortions; this approach would require a sample of only 180 abortuses in order to detect the same doubling.

b) Increased lead time

Another important advantage to the use of studies of spontaneous abortions is the lead time gained for the discovery of an agent which induces abnormality in the conceptus. Since spontaneous abortions generally occur 6 months earlier than term births, they provide an opportunity for earlier detection of hazards.

c) Potential for precise examination of the conceptus

Spontaneously aborted conceptions, unlike liveborn infants, can be examined fully: cytogenetic and pathologic study of the abortus permits specification of the outcomes with rare precision, and in some instances may permit measurement of exposure to the hypothesized hazard.

4. Special Considerations in Studies of Spontaneous Abortions

a) Ascertainment

Ascertainment of spontaneous abortions by definition is limited to spontaneous abortions among recognized pregnancies. Estimates of the frequency of unrecognized spontaneous abortions (that is, spontaneous abortion in which the woman was not aware she was pregnant and in which pregnancy cannot be confirmed by pathologic examination of the specimen) vary considerably. In a recent study [18] where urinary hcG levels were measured on the 3rd week after the last menstrual period, the frequency of unrecognized abortion (raised hcG level, but no other sign of pregnancy) was estimated to be about the same as that of recognized abortion. As understanding of the meaning of these raised hcG levels grows, there is the exciting possibility that an outcome, previously unstudied, can be added to the list of end points set out at the beginning of this report. As yet, however, the determinants of these raised hcG levels are unstudied, and it is not clear whether the causes of recognized and unrecognized abortions are similar.

Several sources of data can be used to identify recognized spontaneous abortions: vital certificate data, hospital records, physician records, interview data from either the woman or her mate. For the most part, vital certificate data will provide an incomplete source of information on abortions occurring before 20-34 weeks gestation, since reporting of these fetal deaths is not required in most states. The completeness of ascertainment from either hospital records or physician records will depend, of course, on the frequency with which medical attention was sought for care of spontaneous abortion, and patterns of service use. Both frequency and type of medical service use are likely to vary between communities, and possibly with socioeconomic variables as well. In a series of women identified for spontaneous abortions in New York City, the frequency with which women sought care for spontaneous abortions varied with gestation. In about 40% of 1st trimester abortions, no medical care was sought. Interview data from the women are likely to provide the most complete ascertainment; however, it has the disadvantage that in some instances episodes of amenorrhea may be reported as spontaneous abortions.

b) Analysis of retrospective data on spontaneous abortions

One approach to enumerating all spontaneous abortions that occurred in a defined population over a defined time period is to obtain information from three sources; the woman, physicians in the area, and hospital facilities. This series of spontaneous abortions will comprise four types of events: spontaneous abortions reported by women with no medical attention having been sought; spontaneous abortions reported by the woman and validated through medical records; spontaneous abortions in which the women report seeking care but no record of this care is found; and, lastly, spontaneous abortions identified in medical records but unreported by the women.

The first two categories (abortions where no medical attention was sought and abortions validated in medical records) are likely to be the largest.

One approach to the analysis is to consider these two (or four, depending on the size of the sample) categories of spontaneous abortions separately; that is, to examine the relation of spontaneous abortion to exposure among women who did not seek medical attention, and women who did. Before this analysis is undertaken, the gestational distribution of abortions in these two groups should be compared, since it is likely that the proportion of abortions under 13 weeks of gestation is higher among women who did not seek medical care than among those who did. Since exposure may lead to abortion at only one period of gestation, gestation should be controlled (possibly in intervals: less than 13 weeks, 13-16 weeks, and 17-28 weeks) in examining the relation of exposure and spontaneous abortion among women who sought medical care and those who did not. Insofar as the association of exposure and spontaneous abortion is similar within gestational groupings for each of these groups of women, the data could be combined to consider the relation of exposure to spontaneous abortion in general, regardless of whether or not medical confirmation was obtained. Insofar as the findings are not similar, the possibility of bias, either in reporting or in care-seeking behavior, must be entertained.

c) Reliability and validity of reproductive histories

In view of the limits set out regarding the use of medical records for spontaneous abortion research, investigators increasingly are utilizing an interview approach, taking maternal and/or paternal reports of reproductive history. There is some evidence to suggest that maternal reports of reproductive events are reliable: that is, interview information is generally compatible with reproductive history data in the woman's obstetric record [19]. It has been hypothesized that paternal recall will be less reliable and precise as to frequency and timing of events than maternal recall. However, there is virtually no evidence regarding the validity (as opposed to reliability) of reproductive history data obtained by interview.

d) Equalizing the period at risk

By definition, spontaneous abortions occur at an earlier gestation than do livebirths. This may present a problem in case-control studies of spontaneous abortion, where controls are term births. In defining exposure status during pregnancy, the period of gestation examined in the control should be confined to that of the referrent case. Failure to do so could result in the spurious finding of an association between exposure and the favorable outcome (term birth), since controls are at risk of exposure for a longer period of time than are index cases.

e) Defining the unit for analysis

The occurrence of one spontaneous abortion increases the risk of abortion in subsequent pregnancies. Thus, conceptions occurring to the same couple are not strictly independent, nor are characteristics of the couple (e.g., age, smoking and alcohol use) which need to be controlled in the analysis of fetal loss. At issue is whether in the study of spontaneous abortions (and some other reproductive end points), analyses should be based solely on the number of couples, or on the number of pregnancies, or some combination of the two.

In the past, some reproductive research has based sample size on the number of pregnancies, ignoring the independence assumption required by the analytic method applied. The practical reason for wishing to use pregnancies as the unit is that frequently (especially when investigating a localized phenomenon) one is able to cull only a small sample of exposed individuals, though each may have had several conceptions. Resolution of this methodologic problem rests on utilizing an analytic technique which controls for the degree of dependence between different conceptions to the same couple. The use of such analytic techniques permits pregnancies, rather than women, to be considered the unit of analyses. Increases in statistical power will usually follow on this increase in the sample size.

D. CHROMOSOMAL ABNORMALITIES

Information on chromosome abnormalities diagnosed at amniocentesis or at birth is sometimes routinely available through special chromosome registries. Examples of this are the New York State-Northeastern Chromosome Registry [23], and the Interregional Cytogenetics Registry System [24].

Participating cytogenetic laboratories in these registries report (anonymously) all information on all amniotic fluid culture results, both normal and abnormal, as well as the parental ages, reason for study, and county of residence of parents. Only abnormal results from diagnostic chromosome studies done on peripheral blood or other tissues are reported to the New York-Northeastern Regional Registry, while all cases, both abnormal and normal, are reported to the Interregional Registry, including detailed information on chromosomal polymorphisms.

New York-Northeastern Regional Registry members include all licensed cytogenetics laboratories in New York State as well as a few laboratories from New England. Reporting of chromosome abnormalities is mandated by the New York State Department of Health, and the Registry is run by the Birth Defects

Institute. The Interregional Registry is supported by NIH funds, and consists of five laboratories across the USA located in New Haven, Connecticut; Albany, New York; Indianapolis, Indiana; Memphis, Tennessee; and Portland, Oregon. (Participation of these laboratories is subject to review by human subject review boards of each institution.)

Since all cases of amniocentesis for chromosome analysis are reported in these registries, they will provide reliable data on the incidence of chromosome abnormalities at 16-20 weeks of gestation for women of a given age who have amniocentesis. The overall incidence of chromosome abnormality in cases coming to amniocentesis is usually about 2%, and is close to twice the incidence seen in livebirths to women of the same age. The difference is partly due to loss of many of these chromosomally abnormal fetuses as late spontaneous abortions or late fetal deaths. The rate of amniocentesis use in women over 35 years varies widely throughout the country, but in the regions served by these registries it is used by about 15-30% of all eligible women on the average. Although women undergoing amniocentesis differ in such things as socioeconomic status from women not undergoing amniocentesis, this is unlikely to influence the frequency of chromosome abnormalities.

While data on the incidence of chromosome abnormalities in livebirths can also be obtained from registries, this is less satisfactory because of uncertainty about the size of the population from which the cases were drawn. Since the New York State Registry includes all registered cytogenetics laboratories in the State, it should include all cases diagnosed out of the total of livebirths in the State, with the exception of the small number of patients who obtained cytogenetic studies across the State line. Since it is rare these days for a diagnosis of Down syndrome to be made without cytogenetic confirmation, and the other autosomal trisomies are also confirmed this way, the ascertainment of cases of autosomal trisomy from cytogenetic laboratories should be almost complete. The incidence of sex chromosome anomalies cannot be obtained this way, since these conditions usually are undiagnosed for many years after birth. The Interregional Registry has an uncertain denominator, since it is unclear what population is served by the large referral hospitals in the registry. If it is assumed that the size of the population at least remains relatively constant, then temporal comparisons can be made in any one region.

Hook has suggested that one can use an intraregistry comparison, the proportion of all livebirths with an autosomal trisomy syndrome which are the result of a sporadic (nonfamilial) chromosome rearrangement, as an index of the rate of chromosomal damage and thus, of mutation, in the population [25]. Using this approach, Hook was able to demonstrate an increase in sporadic Robertsonian translocations occurring over a particular period in the New York Registry.

At the stage of a Level II investigation, the regional incidence of chromosome abnormalities at amniocentesis and at birth can be obtained by canvassing cytogenetics laboratories which serve the populations of interest. The fact that these laboratory services are usually centralized in large medical centers makes this task relatively simple.

E. BIRTHWEIGHT

There is little question that birthweight is the single most accessible and general end point for reproductive failure. Its advantages in many parts of the world are:

It is recorded routinely and with a high level of precision for livebirths. The information is, therefore, available for Level I studies, as well as for more detailed analyses.

It is certainly a sensitive index of several known environmental exposures, for instance, smoking.

It correlates with other outcomes (in particular, curtailed gestation; congenital malformations; late fetal death; neonatal death; sudden infant death syndrome; chromosomal syndromes). Since it is often more uniformly recorded than some of these, it serves as a screen for other outcomes.

It provides a continuously distributed variable with attendant statistical advantages.

Some limitations of birthweight as an end point are:

It obviously omits infertility, very early loss, and often late fetal death from consideration.

It is affected by known personal attributes and habits, like prepregnancy weight, cigarette smoking, and social class, by major differences in dietary intake, and by ethnicity. Therefore, in Level I studies, unless some of these are controlled in making comparisons, results that rely on community comparisons will often be unsatisfactory. On the other hand, Level II studies have a real advantage when studying birthweight, because so much is already known and can be taken into consideration in the design.

As survival rates for very low birthweight infants are by no means uniform, if birthweight studies are restricted to livebirths, distortions could occur. On the other hand, birthweight is less completely recorded for fetal deaths (even late fetal deaths).

Birthweight can often be combined with duration of gestation, and read as "intrauterine growth retardation." Duration of gestation is less precisely recorded for many reasons, one being that real doubt may exist regarding the time of conception. Methods have been developed to overcome this problem. One criticism of these methods is that the women for whom the datum of gestation is less precise differ somewhat sociodemographically from the general population, and applying a correction to the data glosses over these differences.

F. SEX RATIO

Sex of infant among livebirths is as regularly recorded as birthweight, so that sex ratio (no. of males/no. of females) is a widely accessible end point. The at-birth sex ratio is always close to 1, with slight excess of males: in Britain it has fluctuated between 1.03 and 1.06 since 1870. Less data are available at earlier stages of gestation, but data on karyotyped spontaneous and induced abortions indicate that the sex ratio in recognized pregnancies is also close to 1. There are problems with the latter data because of the possibility of maternal rather than fetal cells being examined, but there can be little doubt that the large excess of males once thought to be present in early gestation is not there even as early as 6-8 weeks.

Genetic theory predicts that an induced increase in mutation rates will lead to an excessive loss of males when the female is exposed, and an excessive loss of females when the male is exposed, though these trends will be disturbed by changes in rates of nondisjunction affecting the sex chromosomes. The sex ratio was intensively studied in the atomic bomb survivors, finally leading to the conclusion that differences in the expected direction were not demonstrated.

Differences in sex ratio have been suggested to result from the time of fertilization relative to ovulation. Changes have been found in wartime conceptions, and one study suggested social class differences. Whether these changes related to time of fertilization, or to environmental factors affecting postconception survival is not clear.

G. CONGENITAL MALFORMATIONS

Classification

Congenital malformations are usually classified according to the WHO International Classification of Disease System. This is the system used, for example, in the two monitoring systems described in Section IV above for Level I investigations. For small populations, the rarity of most individual malformations (see Table 8) makes it necessary to attempt to group them in some way; often, the overall rate of major and minor malformations may be the only way to use the data, in spite of the obvious problems with such a heterogeneous grouping (see Section III). A common approach to grouping malformations is by organ systems — thus, one may group CNS defects, facial clefts, limb defects, heart defects, etc. Such a classification may make little sense in a study whose focus is etiologic, since it will inevitably create groups of heterogeneous etiology. It would be better to attempt to identify cases with similar types of cause, e.g., known single gene defects, chromosomal defects, known environmental causes, multifactorial situations, etc. This is difficult in practice without extensive history taking and examination of the patients. However, it may sometimes be achieved using hospital records, and could be attempted at a Level II investigation.

Table 8
COMMON MAJOR MALFORMATIONS AMONG NEWBORN INFANTS

ICD #	Malformation	Rate per 1000
740.0	Anencephaly	1.04
741.9	Myelomeningocele	.33
742.3	Congenital hydrocephalus	.36
745.1	Transposition of the great arteries	.26
745.4	Ventricular septal defect	1.17
746.7	Hypoplastic left heart	.23
747.0	Patent ductus arteriosus	.72
749.0	Cleft palate	.33
749.1	Cleft lip and cleft lip with cleft palate	.78
752.5	Undescended testes	1.21
752.6	Hypospadias — first degree	2.12
752.6	Hypospadias — second or third degree	.52
	Clubfoot — all types	2.05
754.51	Talipes equinovarus	1.01
754.53	Metatarsus adductus	.49
754.6	Calcaneovalgus	.55
754.3	Congenital dislocation of the hip	.78
755.0	Polydactyly — Type B	2.15
758.0	Down syndrome	1.53

Prevalence of all major malformation is 26/1,000. These data are derived from surveillance of 30,681 infants of at least 20 weeks gestational age born at Boston Hospital for Women.

Other classification schemes based on the embryologic process involved in the formation of the defect may also be considered as our knowledge of these relationships increases.

The advantage of a meaningful classification scheme is to permit refinement of the malformation variable. For example, if 1st trimester exposures are being considered, inherited single gene defects, chromosomal anomalies and defects due to postural abnormalities in the 3rd trimester may be ignored.

It has been suggested that certain dominantly inherited traits could be used as "sentinel phenotypes," so that monitoring the incidence of new noninherited cases could reveal a change in the mutation rate. Such a condition would have to be readily diagnosable at birth, be relatively free of heterogeneity, and have a high rate of penetrance. Classic achondroplasia, polydactyly, and the acrocephalosyndactyly syndromes have been suggested as possible candidates, although all are unsatisfactory for one reason or another, in our view.

Methods of Study

The observed incidence and variety of congenital malformations will vary depending upon the age, race, and sex of the patient examined, and the methods used for examination. A trained, motivated, systematic examiner will find a much higher rate of defects, and an autopsy will always reveal more malformations. An appropriate control group must take all of these factors into account. If both exposed and unexposed children are to be examined, the observer should be unaware of their exposure status.

In Level I or Level III studies, it may be possible for children at risk to be examined by special study physicians. These should be trained in the identification of major and minor congenital anomalies, and in syndrome recognition. The examination should be conducted using a checklist of features (for example, see Table 9). A decision must be made beforehand whether to include minor anomalies in the study, and whether to include examination for internal anomalies, such as heart defects or abnormalities found only at autopsy. Chromosome analysis should be carried out if possible on all children with any two of growth retardation, multiple anomalies, or mental retardation.

The identification of a consistent pattern of malformations as the result of a particular exposure is convincing evidence of a real effect. The recognition of such a "syndrome" should then be one of the goals of a Level II investigation of malformations. However, it is also possible for the effects of a particular exposure to vary, ranging from spontaneous abortion to congenital defect, to growth retardation, and to behavioral abnormalities. The effects may vary with dose and time of exposure, as well as with other fetal and maternal factors.

H. PERINATAL AND INFANT DEATHS

In the United States, late fetal deaths (stillbirths), neonatal and postneonatal deaths are well recorded, although gaps have been demonstrated. Also, several states link death certificates for infants dying in the first year of life with their birth certificates, making an invaluable data source available to Level I investigations.

Perinatal deaths are strongly influenced by socioeconomic status (which may be related to role of exposure); they also reflect the incidence of malformations, of low birthweight (<2500g), and increasingly, of very low birthweight (<1500g).

Therefore, the more useful end point seems to be birthweight. Although the rate of survivors among very low birthweight infants shows considerable temporal and geographic variability, this variation today is mostly considered to relate to level of medical care.

One study suggested that a pollutant of water was related to perinatal deaths for low birthweight infants. And some studies show that maternal smoking not only increases the rate of low birthweight babies but also adds to the mortality experienced by them.

The risk of sudden infant death is increased by low birthweight, and by maternal smoking.

I. TRANSPLACENTAL CARCINOGENESIS

Introduction

To our knowledge, environmental agents seldom cause cancer during childhood. The main reason may be that latent periods are usually longer than the 15 year pediatric span.

The shortest latent period known for a human cancer is 2 months — for lymphoma after immunosuppression for renal transplantation. In theory, infants might be born with lymphoma because their mothers received immunosuppressive therapy during pregnancy. A substantial number of women have been so treated, but we know of no lymphomas in their children.

Cancer can, of course, be present at birth. The incidence in the U.S. during the first month of life is about 37 per million livebirths [26]. We do not know environmental causes of such tumors, with one exception: neuroblastoma at birth in a child with the fetal hydantoin syndrome [27]. Four children are known with this combination of disorders in the U.S., 1976-1980. The experience illustrates the possibility of identifying environmental carcinogens by either concurrence of cancer with syndromes known to be due to specific environmental agents, or through the maternal history when congenital tumors are observed. The possibility of an environmental cause would be enhanced if time-space clusters of specific congenital tumors were observed.

Diphenylhydantoin is apparently the second transplacental human carcinogen identified, the first being diethylstilbestrol (DES). Here, a cluster of a rare tumor of the cervix or vagina in young women in Boston led to recognition of the contributing role of DES. As usual, the environmental pathogens were identified by simple retrospective studies. Some prospective studies of DES have been made, but the frequency of cancer in daughters is too low to be determined precisely. But of those taking the drug during pregnancy, only about one in a thousand of their daughters developed cervical or vaginal cancer [28]. Instead of seeking details of the exposure and natural history through prospective studies, a special national disease registry for patients with DES-type tumors was established. Information about the interval of susceptibility during pregnancy, and about pathogenesis was obtained in this way.

Methods of Study

Teratogens and carcinogens are almost always first detected by alert clinicians. A causal relationship suggested by a series of clinical observations can sometimes be tested by study of data in tumor registries or in prospective studies conducted for a general health surveillance. Thus, DES was confirmed as a transplacental carcinogen by data from the New York State Tumor Registry. And knowledge of the fetal alcohol syndrome was extended by study of data already collected in the collaborative Perinatal Study of the NICDS. Thus, these resources can be used more to amplify relationships than to detect them in the first place.

When an exposure is suspected to be carcinogenic and a substantial population of children have been exposed, one can match identifying information of the population at possible risk against tumor registry data or against the National Death Index [29]. In this way, follow-up will be simplified. A unique number for each person would greatly aid in matching. Adults usually have Social Security numbers, but children do not. Attention should be given to providing such numbers at birth, a suggestion made for the U.S. at least as long ago as 1968. Recording the mother's maiden name and her Social Security number can be of great assistance in follow-up of children.

Regional excesses in mortality from specific cancers can be informative in identifying environmental causes of adult neoplasia, e.g., asbestos exposure of shipyard workers during World War II as a cause of increased lung cancer in cigarette smokers in coastal Georgia. Childhood cancers are probably insufficiently frequent for detection in this way of transplacental carcinogens.

Problems in Studying Transplacental Carcinogens

We can reason that any agent that can cause cancer in adults and is known to cross the placenta may cause cancer in the offspring, including constituents of cigarette smoke, immunosuppressive drugs, and benzene. None are (yet) known to be transplacental carcinogens. Perhaps the cancers they induce are among the more frequent types and long delayed in their onset. Both of these circumstances would mask their detection. Diphenylhydantoin occasionally causes lymphoma in persons using the drug for epilepsy. One would expect children with the fetal hydantoin syndrome — due to the same drug, to be prone to lymphoma. Instead, unaccountably, they develop neuroblastoma.

Finally, it should be pointed out that clusters of specific cancers in children may lead to the detection of an environmental carcinogen, such as DES, but many excellent studies of leukemia clusters in childhood have failed to reveal an environmental cause. Leukemia is frequent enough to cluster often by chance in a country as populous as the United States. Vaginal cancer in young women is too rare for such clusters to occur, thus explaining the difference in the two experiences.

The detection of cancers from transplacental chemical pollutants will perhaps best be recognized in the future as such occurrences have in the past; namely, by alert clinicians practicing in the area where a new environmental agent has been introduced.

SECTION IX

SUMMARY OF PUBLISHED DATA AND AN ANNOTATED BIBLIOGRAPHY ON EXPOSURES AND REPRODUCTIVE FUNCTION

The following tables are an updated version of those originally appearing in an article by Strobino, Kline and Stein (J Early Hum. Devel 1:371-399, 1978). The papers summarized in the tables represent a selected bibliography. Special attention was given to original and early reports, and also to recent reports. An attempt was made to include all population studies: case reports were included if they were numerous, or where the effects seemed highly specific in relation to a particular agent.

THE TABLES

Criteria for selection

We have tried to locate all reports in the scientific literature in 1976 and the previous 10—15 years that related detrimental effects in humans to parental exposures to chemical and physical substances. A bibliography was compiled from our own reading, from consultation with colleagues (see Acknowledgements), from annotated reviews of special areas, Medline searches and the Index Medicus.

From this bibliography we selected the papers summarized in the tables. Special attention has been given to early and original reports, and also to those published in the current period. We have tried to include all population studies, whether the associations reported were present or absent or inconclusive. With regard to case reports, we have included those where the case reports were many, or where the effects seemed highly specific in relation to a particular agent.

Key to the tables

The effects of each supposedly hazardous agent are summarized in Tables I—III.

+ indicates that the investigation was based on population groups and that it demonstrated a statistically significant association. + may also refer to a study based on multiple case reports of a highly specific outcome (e.g. fetal alcohol syndrome).

0 indicates that no association was demonstrated.

+/0 indicates that the results of a study were inconclusive because the data were conflicting or statistical tests were of borderline significance.

+? indicates that an association was demonstrated but only on the basis of single case reports, or of population studies in which the study design was seriously flawed. 'Serious' flaws include such features as lack of a control group or no consideration of statistical significance.

The problem of power (0)

In considering studies marked 0 in the tables, we found that little or no attention had been given to the statistical power of a study. Power is the probability that an effect, if present, will be detected. The power of a study is determined by the frequency of the outcome variable in the unexposed population, the size of the effect expected, the acceptable level of significance, and the sample size [1,2]. The frequency of developmental disability is always low in the unexposed population. Also, the size of the effect to be expected from exposure to a mutagen or teratogen is usually small. By a small effect we mean, for example, that there is a relative risk of

1.3 when exposed individuals are contrasted with unexposed individuals. Very large sample sizes are therefore required before an investigator can, with confidence, accept the null hypothesis that there is not even a small effect.

Insufficient numbers and a failure to consider power undoubtedly explain some of the many inconsistencies between studies that are noted in the tables. Taking the investigations of maternal irradiation and leukemia as an example, several investigators [108–109,111–113] have shown that children exposed to diagnostic irradiation in utero have an increased risk of developing leukemia or other malignancies in later life. Kato [107] was unable to confirm these findings in survivors exposed in utero to the A-bomb even though the dosage was extremely high. One explanation is that the exposed population, 1300, is of insufficient size to detect a relative risk of 1.4 — 1.6. The power is, in fact, well below 75%.

If the expected incidence of an outcome in an unexposed population is 0.001, and the risk of the outcome is doubled in exposed individuals, then a population of 10,100 exposed individuals must be studied in order to have a 75% probability of demonstrating a difference significant at the 5% level (using a two-tailed test). In this calculation we have assumed that the expected incidence is constant and that data on an unexposed sample will not be needed. If this assumption cannot be made and two samples (exposed and unexposed) are required, then one would need 20,195 individuals in each sample to detect a relative risk of 2.0.

Of course, if exposure is always or almost always associated with detrimental effects, these considerations become unimportant. They do weigh heavily, however, if a particular exposure is announced to be 'not a hazard', on the basis of an inadequate study.

I. BACKGROUND AND INTRODUCTION

Man is exposed to a rapidly increasing variety of synthetic chemicals in the environment. Among the agents represented in this proliferation of chemicals are some which have mutagenic effects. The list of chemicals for which there is experimental evidence of genetic activity has expanded rapidly during the last two decades. While mutation contributes to the genetic diversity of a species, there is reason to believe that spontaneous mutation rates are sufficient to maintain the genetic variability of the human population. Furthermore, substantial evidence indicates that induced increases in the mutation rate could produce a general decline in genetic health.

Since the consequences of exposure of human populations (or those of other species) to mutagenic agents occur long after a chemical is introduced into the environment, early identification of potential hazards is crucial to minimizing exposure and resultant risk. Consequently, a number of agencies of the federal government, as well as private industry and academic institutions, have exerted considerable effort in the development of efficient and effective methods for the detection of mutagenic agents. Preliminary efforts also have been made to evaluate quantitatively the relative potency of mutagens and the implications (risk) of mutagen exposure for public health. Such attempts at mutagenic risk assessment, however, are at an early stage of development.

The task of assessing risks associated with chemical mutagens is extraordinarily complex because of the great diversity of mutagenic agents, and the multiplicity of ways in which they can interact with biologic systems. Chemical agents are known to have genetic consequences both by inducing alterations at the chromosomal level and by inducing mutations at the single gene level. Chromosomal alterations, as described in Panel I Report, include changes in chromosome number (aneuploidy and polyploidy), and changes in chromosome structure (deficiencies, translocations, duplications, and inversions). Gene mutations can result from base-pair substitutions, frameshift mutations (additions and deletions of base pairs), or multilocus deletions. All of these genetic events may have serious implications for the genetic welfare of man.

Human genetic disorders attributable to alterations in chromosome number (aneuploidy) include Down syndrome (mongolism), Klinefelter syndrome, and Turner syndrome. In the majority of cases, these conditions are attributable to devise, develop, and use test approaches which detect and evaluate mutagenic potential, and there is a concomitant need for human population monitoring for potential mutagenic hazards.

The need to develop screening programs to detect environmental chemical mutagens is emphasized in the Environmental Mutagen Society position paper known as the Committee 17 Report [2]. These programs should address our needs to both identify approaches to the assessment of mutagenic potency as well as to provide a data base for the overall toxicologic safety evaluation process. Toward the latter objective, the U.S. Environmental Protection Agency has established the "Gene-Tox Program" for assessment of the current status of bioassays in genetic toxicology. The results of tests on more than 2,800 chemicals in approximately 39 genetic bioassays have been evaluated and encoded for computer analysis in the near future [3].

A. SUSCEPTIBLE POPULATIONS

The conditions described in the previous section are multisystem disorders involving abnormalities in the skin, brain, immune system, skeleton, etc. With the disorders involving repair deficiency — ataxia telangiectasia (AT) and Fanconi anemia — molecular explanations for the cellular observations are rapidly evolving, but there is at present no obvious relationship between the different defects in DNA repair and most of the clinical signs of the disorders. It is important to determine whether these signs are the result of damage to DNA and if so, whether this damage is produced intrinsically by the human body or by extrinsic agents.

No defect in DNA repair has as yet been discovered for Bloom syndrome, but the similarity of many features to those of Fanconi anemia and AT makes it likely that such a defect eventually will be revealed. Assuming that this is the case, the occurrence of a DNA repair defect, chromosomal instability, frequent immune defects, and a high incidence of cancer in Bloom, Fanconi, and AT patients suggest that these disorders and signs are related. The study of the molecular basis of these diseases is only in its infancy, and further experimentation will no doubt provide further examples of repair-defective human conditions which will aid in elucidating the mechanism of repair and mutagenesis, and also hopefully of carcinogenesis.

The molecular and cellular studies described above have certain direct clinical applications. They can provide the possibility of early (even prenatal) diagnoses and of a *reliable* diagnosis before the onset of the full clinical symptoms; for example, before XP patients have developed tumors. In the case of AT, the cellular studies suggest that full doses of radiotherapy should be avoided. They also have the potential of ascertaining which, if any, forms of chemotherapy might be similarly contraindicated.

The diseases themselves, despite their rare occurrence, are of general importance. The epidemiologic studies of Swift have suggested a possible increase in the incidence of cancer in AT and Fanconi heterozygotes [1]. He has estimated that such heterozygotes comprise approximately 1% of the population. The high incidence of cancer in these individuals may be a significant proportion of the total cancer incidence in the general population. Identification of such heterozygotes, for example by increased cellular or chromosomal sensitivity to chemical mutagens, would allow monitoring for cancer in subjects at risk.

II. THE NEED FOR GENETIC MONITORING

Although human populations are not deliberately exposed to potential mutagens in order to measure mutagenicity, there nevertheless are circumstances in which observations can be made directly on humans. These most often occur because of occupational exposure or administration of therapeutic drugs. In these instances, the typical approach is to identify an exposed group and a suitable control group for comparison of some genetic effect. The experimental design is thus similar to that used with other organisms. The numbers of persons required may be small or very large, depending on the test used.

A different situation occurs when a population is to be monitored to detect an increase in mutations over time, usually with no suspect mutagen in mind. In this instance, the population serves as its own control, the rate at one time being compared with the rate at another. Again, the population required may be large or small, depending on the mutational parameter being assessed.

It is the general goal of population monitoring and testing to develop efficient systems that require fewer persons and resources; a goal that, at present, is far from achievement. In considering tests that might be applicable to humans, some limitations are obvious compared to experimental mammals. No test is acceptable that requires administration of hazardous materials, such as radioactive compounds or mutagens. Furthermore, biologic specimens are limited to body fluids the occurrence of meiotic nondisjunction in a parent of the affected individual. Such nondisjunction leads to the formation of germ cells having too many (Down syndrome and Klinefelter syndrome) or too few (Turner syndrome) chromosomes. Collectively, these and other clinically serious chromosomal abnormalities in man are estimated to occur with an incidence of 0.5% among total live births in the United States. In this context, it is noteworthy that Down syndrome is the most frequent, single definable cause of severe mental retardation. While the relationship between chemicals and the incidence of aneuploidy in man is uncertain, exposure to mutagens has been shown to increase the frequency of occurrence of aneuploids in several experimental organisms. Besides causing genetic abnormalities in children and adults, variations in chromosome number can lead to spontaneous abortion of affected human embryos, as mentioned previously in this book. It has been estimated that approximately 20% of all spontaneous abortions involve chromosomal defects, the etiology of which is unclear. Among such defects are both aneuploidy and polyploidy.

In addition to alterations in chromosome number, structural changes in the karyotype can have severe consequences. Among human disorders associated with such structural alterations are cri-du-chat syndrome (due to a deficiency), and a form of Down syndrome (involving a translocation), less common (about 5% of all cases) than the simple aneuploid type. A number of other rare but severe abnormalities are ascribable to structural aberrations in chromosomes. With recent major advances in cytogenetic techniques, there is now a much enhanced capability to detect chromosomal alterations in man. It is likely, therefore, that the proportion of disorders which can be associated with chromosomal damage may increase in the future. Significantly, it has been known for many years that mutagens can induce karyotypic abnormalities in a diversity of organisms.

Gene mutations can have a variety of effects depending upon the mechanism of gene expression. It should be noted, moreover, that the effects of gene mutations overlap with those of small deletions which may involve a chromosomal region larger than the confines of a single gene, and the two types of alterations may not always be readily distinguished. For simplicity, we can view gene mutations as changes which give rise to alterations in gene products or no product at all (null mutations). Depending upon the mode of genetic expression, the resultant mutant alleles may behave as dominants or as recessives. Also, several other types of dominance relationships are known to occur.

The relationship of the induction of gene mutations to human health is supported by the existence of a large number of genetic diseases which may be attributed to mutant alleles of a gene. Among the many dominant genes known in man are a number of alleles responsible for physical anomalies and malformations as well as other aberrant conditions. Included are some cancers referred to as hereditary neoplasms: the most thoroughly studied hereditary neoplasm is bilateral retinoblastoma, reported to occur with a frequency of 1/20,000 births.

The total disease burden attributable to dominant gene mutations has been estimated to be similar to that for chromosomal defects, approximately 0.5%.

Recessive mutant alleles are also of major importance with respect to human genetic disease. There are over 1,000 known genetic disorders which have the heritable properties of recessive gene mutations. Among these are such well-known diseases as sickle cell anemia, cystic fibrosis, and Tay-Sachs disease. Since an individual expresses a recessive characteristic only if he receives the recessive allele for that characteristic from both parents, many individuals undoubtedly carry deleterious recessive genes without expressing the corresponding disease state. In fact, carriers of deleterious recessive alleles typically far outnumber those with the disease, and most individuals probably carry at least one deleterious recessive [1]. Therefore, induced recessive mutations may remain unexpressed for a number of generations until a mating occurs in which both parents are carriers of a recessive allele for the gene in question. An offspring receiving the recessive allele from both parents would express the corresponding characteristic. There is concern among geneticists that exposures to new mutagenic agents in the environment could be increasing the genetic load of the human gene pool, and that the irreversible damage, which takes the form primarily of new unexpressed recessives, can lead to an increasing incidence of genetic diseases in future generations. Surveys of the pediatric wards of major metropolitan hospitals have revealed that at any given time 5-6% of the patients are suffering from diseases caused by single-gene defects — the result of homozygosity for recessive gene mutations. No estimates are available, however, concerning the fraction of these cases attributable, in whole or in part, to new mutations, as opposed to mutations derived through many generations of human evolution.

Taken in their totality, diseases of genetic origin are of major importance to human welfare. They can lead to debilitation and/or death and to the concomitant human suffering. It has been estimated that *at least* 10% of all human disease appears to exhibit a significant genetic component.

The contribution of chemical agents to the human genetic disease burden, either as it exists now or as it is likely to exist in the future, is highly debated. Concern over the possibility that certain chemicals may pose a threat to the integrity of the human genome and thus to future generations is predicated on sound theoretic reasoning. While definitive proof is lacking, there is little doubt that many chemicals have the potential to induce human mutations. Although man has evolved through thousands of generations with mutagenic agents present in the environment, the number and spectrum of such agents has increased markedly in our recent history due to the industrial revolution and recent technologic developments. Although we are still exposed to many naturally occurring mutagens, we are now also exposed to many man-made chemicals, some of which have mutagenic activity. This new type of exposure may be inflicting significant genetic damage in man. Because of this concern, there is a need to such as blood and urine or expendable cells such as blood cells, hair follicles, and sperm. These restrictions rule out some tests that are used in other organisms or in cell culture systems.

The development of systems to monitor human populations for genetic effects should be undertaken for several reasons: 1) there is a burden of human disease of genetic origin, and a consequent need to identify and eliminate causes of these disorders, where possible; 2) there is a likely role of genetic damage in the etiology of cancer; 3) the potential magnitude of environmental exposures to mutagenic substances and animal data suggests that such exposures may result in somatic and heritable mutations; 4) there is a need to diminish latency in detection of damage to man from these environmental exposures; 5) there is a need to compare findings in man directly with those derived from animal and short-term tests, thereby improving our ability to assess human risk based on non-human studies; and 6) there is a need to identify individuals unusually susceptible to genetic damage because of differences in repair capacity or metabolism. The background for the following discussion has been provided by others elsewhere [2-8].

Direct measurement of genetic damage in man by standard epidemiologic studies is difficult. Such studies typically employ the incidence of spontaneous abortion, congenital defects, or malignancy as an indicator of genetic damage: each of these end points has marked limitations. Thus, a feasible, properly validated group of assays which directly evaluated genetic damage in man would be of great value to us in our assessment of risk from mutagen exposures.

Laboratory-based monitoring techniques should make it possible to detect genetic hazards from environmental exposures sooner and after lower exposures than is currently required. The latency problem is well illustrated by the history of the detection of health effects from smoking. Cigarettes began to be consumed in large numbers around 1900; but it was not until the mid 1920s that death rates for lung cancer increased, and another 20 years before the association of these events was made. If similar delays occur in disease onset and detection of causal associations resulting from the exponentially increasing production of chemicals in the past two decades, the public health impact may be severe, though unknown for many years. A program of laboratory monitoring to detect these events prior to their clinical manifestation is obviously highly desirable.

Finally, although recently developed efficient and reliable batteries of mutagenesis tests have demonstrated that many chemicals are capable of causing mutation, extrapolation of these test results to human health effects is difficult. Development of parallel tests for genetic damage that can be applied both to man and to mammalian or submammalian systems might allow a direct comparison of human, and non-human findings. Where they can be undertaken (for example, among patients receiving chemotherapeutic drugs), such comparisons may provide important information for extrapolating risk to situations where direct comparisons are not feasible.

The need for monitoring goes beyond techniques to monitor cytogenetic abnormalities and reproductive events described in earlier sections of this book. As discussed in those sections, cytogenetic tests probably will not detect the full spectrum of genetic damage (e.g., may not detect gene mutations), and are costly. Reproductive effects frequently are not specific indicators of genetic damage and typically require monitoring large reproductively active populations. Because effective evaluation of human populations exposed to genetic and reproductive hazards probably starts with consideration of these effects, we have included cytogenetic and reproductive end points for comparison in our tables and briefly in the discussions that follow.

III. CRITERIA FOR DEFINING A HUMAN POPULATION AT RISK

Exposure of human populations to hazardous chemicals produced by modern technology has been well documented. Based on the exposure and probable health effects, these populations can be divided into three groups: 1) low-risk; 2) likely-at-risk; and 3) at-risk. Low-risk populations are those who have no known exposure to hazardous agents.

Two types of populations likely-at-risk are those who have been exposed to 1) a known mutagen and/or carcinogen, or 2) mutagenic complexes or mixtures.

The mutagenic activity of known compounds can be determined by submammalian and mammalian assay systems. Mutagenic complexes and mixtures can be detected by mutagenic monitoring of the environment. Populations groups, such as industrial and chemical workers, hospital personnel, patients, etc., might be exposed to known mutagenic and/or carcinogenic compounds. Accidental exposure of a population to a known mutagen can also occur. Many workers, as well as residents in heavily industralized areas or in the vicinity of toxic waste dumps, may well be exposed to mutagenic compounds or mixtures of such compounds. The degree of the potential risk depends both upon the nature of the mutagenic compound or complex and the level of exposure.

Human mutagenic-monitoring studies should be performed for the population groups which are at-risk or likely-at-risk. Low-risk populations should be used for control studies as they establish baseline data for the given assay system. Mutagenic monitoring of the at-risk population may determine the association between genetic damage and particular health hazards in a human population. Establishment of the relationship between findings from mutagenic monitoring and from epidemiologic studies can eventually lead to quicker and better identification of potential risk and thereby provide greater protection of the human population from health hazards caused by mutagenic agents.

Likely-at-risk populations are the most diverse groups because of the different levels and types of exposures. The priority for the selection of these population groups for the mutagenic monitoring study is ranked as follows:

1. Exposed to high dose(s) of potent mutagens and/or carcinogens
2. Exposed to highly mutagenic complexes or mixtures, at unknown dose(s)
3. Exposed to low dose or to weak mutagens and/or carcinogens
4. Exposed to low dose or weak mutagenic complexes or mixtures.

Mutagenic monitoring of the population likely-at-risk could provide direct evidence as to mutational damage in exposed populations; could identify population groups for epidemiologic studies; and could provide biologic dosimetry for adverse health effects.

IV. METHODS POTENTIALLY USEFUL FOR EVALUATING HUMAN POPULATIONS EXPOSED TO MUTAGENIC HAZARDS

A. Body Fluids

A summary of methods potentially available to monitor human populations for genetic effects is provided below and in Tables 1 and 2. A description of specific assays follows in Appendix I.

The first method listed is for the detection of human exposure to mutagenic substances by the analysis of body fluids. (This technique might be used in conjunction with environmental sampling and chemical analysis, which was deemed beyond the scope of this report.) The most widely used bioassay technique (described in the Appendix) involves concentration of the sample by resin extraction and testing the sample for its ability to mutate bacteria.

The bioassay procedure provides a moderately sensitive test for the presence of mutagenic activity in body fluids. It is generally not as sensitive as standard analytic methods for chemical detection, but has the following advantages: 1) multiple substances and metabolites will be active in a single assay, enabling the detection of mutagenic activity from unanticipated sources; 2) the biologic activity is demonstrated, rather than simply the presence of substances; and 3) the assay may also tend to "integrate" the effect of multiple substances, although this capability has not been well characterized. The chief difficulties with this test are: 1) lack of sensitivity for certain specific substances compared with chemical techniques, 2) the decomposition of mutagens during storage or loss during extractions, and 3) limitations on our ability to concentrate a specimen. Also, solutions must be found to technical problems such as materials in the mixture tested causing toxicity or increased growth of tester organisms.

Alternately, chemical analysis of body fluids for specific mutagens may be undertaken. A technical description of these procedures is not included here. Chemical assays would be most appropriate for demonstrating exposure with established analytic techniques when specific substances are known to be in the environment, but the extent of human exposure is unclear. Biologic assays are most useful when exposures are suspected but the specific suspect chemicals (or possible interactions between chemicals) are uncertain, or when chemical analytic techniques are not available. It must be recognized that both the biologic and chemical approaches require that the mutagens enter the body fluid being tested. In most instances, exposure of other body compartments cannot be confirmed.

B. Expendable Tissues

Laboratory tests to detect genetic damage in specimens of human blood, sperm, or other tissues constitute a second means of evaluating humans exposed to mutagenic hazards. Potential tests are listed in Table 1. These techniques differ by: 1) the genetic specificity of the damage, which ranges from specific effects on chromosomes or DNA to indirect measures (such as alkylation of hemoglobin or altered sperm morphology); 2) the directness with which damage is assessed, from direct physical evidence of damage (DNA adducts, sequence changes, or chromosomal aneuploidy), to evidence of response to that damage (DNA repair or chromatid exchanges); and 3) the size of the genetic unit studied, from single nucleotides of DNA, to single genes, to entire chromosomes. These assays also differ in their statistical power to detect damage, and in the likelihood of their being affected by artifact, but little information is available to suggest the magnitude of these factors.

Table 2 describes the application of these tests to the measurement of damage in somatic tissue, germinal tissue, and offspring of exposed individuals.

Somatic tissue analyses generally utilize readily available blood products (typically peripheral lymphocytes). Sperm is the only readily available germinal tissue which excludes the sampling of women and possibly introduces sizable participant bias. Damage in germinal tissue, however, more clearly implicates risk of heritable effects — at least to the extent of demonstrating access of the active agents to germ cells.

Techniques for detecting damage in somatic or germinal tissues allow analysis of much smaller populations than techniques examining offspring. Monitoring offspring, however, provides the only direct test for inherited effects.

Further specifics of these assays are discussed in the Appendix. As noted above, cytogenetic methods and population monitoring techniques primarily described elsewhere in this report were included in these tables for completeness, but will not be discussed in the Appendix.

V. CURRENT STATUS OF THE USE OF MUTATION ASSAYS TO EVALUATE HUMAN POPULATIONS*

Given our limited understanding of, and experience with, direct laboratory tests for mutation in man, current use of these tests should be limited largely to studies aimed at evaluating the tests rather than evaluating exposed human populations.

The current practical uses of these tests in evaluating populations are probably best limited to the following:

1. Use of tests for mutagens in body fluids to seek evidence of exposures. Situations in which this appears to be of most value are when human mutagen exposure is suspected but not documented, and exposures are mixed, unknown, or when analytic chemical techniques are not available for the suspected compounds. From the onset it must be recognized that evidence of an exposure, not a demonstrated health effect, is being sought. Possible confounding exposures (e.g., smoking) require consideration, and test results must be statistically sound before the conclusion is reached that exposure to an environmental mutagen has occurred.
2. Testing small-to-moderate sized populations for unscheduled DNA synthesis, hypoxanthine phosphoribosyltransferase (HPRT) activity in peripheral lymphocytes, sperm morphology, and double Y bodies in sperm is currently technically feasible. However, these tests are presently of limited utility in assessing genetic risk. This is because the techniques for these assays are a) not sufficiently established to preclude technical problems or confounding factors in the populations studied which may affect results; b) the biologic validity of these tests as measures of specific genetic damage is unclear; and c) the health implications of findings in these assays are unknown.

---

* This discussion excludes cytogenetic and reproductive studies which are considered elsewhere.

3. Large populations can be tested for electrophoretic variants in the blood of offspring. Of the currently feasible assays, this approach alone indicates an inherited gene mutation (although transmissibility has not been tested). The test is limited by the need for sampling large populations. The size of these populations may preclude testing of groups with specific exposures, limits ability to control for confounding exposures, and makes the technique logistically difficult.

TABLE 1. Possible Methods for Evaluating Human Populations Exposed to Mutagenic Hazards by Effect Monitored

Description of Test	Intended to Monitor
EXPOSURE	
Mutagens in body fluids	Direct exposure
Analytical chemistry of body fluids	↓
LABORATORY EVIDENCE OF GENETIC DAMAGE	
Hemoglobin alkylation	Protein damage
Damaged DNA bases in urine	DNA repair

APPENDIX I

DESCRIPTION OF ASSAY SYSTEMS FOR HUMAN POPULATION MONITORING TO DETECT GENE MUTATIONS AND DNA DAMAGE

A. Measurement of Exposure
B. Measurement of Damage
C. Measurement of Somatic Cell Mutations
D. Measurement of Germ Cell Mutations
E. Measurement of Germ Cell Mutations in F_1 Progeny

A. MEASUREMENT OF EXPOSURE

Mutagenicity Assay of Body Fluids

A presumption of genetic hazard can be made if it can be shown that mutagens are circulating in the blood or are present in other body fluids. This is most readily done by testing the mutagenic activity of blood or urine in microbial systems or in in vitro cell culture systems [1,2].

Although it is not possible to equate mutagenicity of body fluids with actual mutation in the host, it is reasonable to assume that such persons are at increased risk of mutation. An increase in mutagenicity can be detected in single individuals, making the test especially useful in assessing exposure of small groups.

Potential confounding sources of genotoxic activity in body fluid samples include drugs, foods, beverages, and life-style factors such as stimulants, skin lotions, cosmetics, and suntan oil. Hence, studies in children may be particularly useful [2a]. In some cases, mutagenic derivatives of chemicals are excreted in biochemically conjugated forms, so that it is necessary to liberate the active genotoxic with enzymes. Certain chemical classes of genotoxins, such as those with short half-lives (i.e., nitrosamines), may not be detected by body fluid tests. Developmental efforts will be required to determine which classes of occupational hazards can be detected with body fluid tests.

Since blood and urine samples may be routinely collected during medical examinations, body fluid testing may be routinely integrated into a medical monitoring system. A battery of different genetic assays might be employed in order to detect the spectrum of potential genotoxic damage. The optimal methodology for a newly discovered hazard could be explored in laboratory animals when initial results are suggestive. The range, sensitivity, and specificity of these methods remain to be established. The costs of body fluid tests should be relatively modest. After a body fluid test achieves recognition as a useful surveillance tool for exposure to a chemical or a class of chemicals, it could substantively contribute to the prevention of occupational disease.

The urine analysis method is readily applicable to human monitoring situations at the present time for the following reasons:

1. Preliminary studies in humans have demonstrated that mutagens can be detected in the urine of humans exposed to various therapeutic drugs, industrial chemicals, and cigarette smoke under typical exposure regimens (Table 1). Thus, the application of this technology has been documented and knowledge of the normal background noise can be estimated;
2. Sample collection for urine is noninvasive and can be readily obtained from both sexes on a repetitive schedule;
3. Biologic analysis can be coupled to qualitative and quantitative chemical analysis;
4. Dose-response studies can be performed on target "indicator" cells of several phylogenetic levels including human cells, if desired;
5. Cost and performance time associated with this approach are amenable to large-scale sampling studies.

TABLE 1. Examples of Human Monitoring Using Urine Analysis

Workmen	Coke production	–	Moller and Dybing, 1980 [8]
Workmen	Epichlorohydrin	+	Legator et al., 1978 [1]

* Microbial target cells employed in all studies.

One of the advantages of the urine analysis approach is the ability to process the urine samples before testing. Organic compounds can be concentrated in urine by passing the urine over sorbent resin columns such as XAD-2. Enzyme treatment of urine samples with sulfatases and glucuronidases will result in the release of conjugated chemical species. Thus, the potential for enhancing the responses of whole urine samples is very good with this method. Similar types of sample processing can be applied to fecal extracts. It should be noted, however, that sample processing techniques may introduce artifacts, and results must be interpreted with care. Blood has been studied less often but can be studied with appropriate modification.

A drawback to these types of assays is the inability to measure cumulative exposure. Of equal importance is the inability to translate the results into a quantitative risk, either for individuals or populations. Nevertheless, this test shows promise of being important in evaluating human exposure to many mutagens.

Detection of Chemically Damaged DNA Bases in Urine

Chemically damaged DNA bases may be solubilized by excision repair or by generalized nucleic acid breakdown and may be excreted via the urine in relatively undegraded states. Löfroth et al [9] noted the excretion of methylated purines following exposure to dimethyl sulfate and proposed that these compounds originated from methylated nucleic acids. Currently available chemical separation and identification techniques can detect such bases in experimental animals following the administration of large doses of alkylating agents. Such large doses are expected to be rare and extreme in human populations, and far more sensitive methods are desirable for human monitoring. Developmental work is underway at the University of California at Berkeley (B.N. Ames, personal communication) to adapt and combine sophisticated chromatographic separations and ultrasensitive mass spectrographic methods to resolve and measure large numbers of urine fractions. (At present, the ribosidic but not the nonribosidic fractions can be analyzed. A large number of expected base alkylation adducts have been prepared for model studies.) The general method is likely to be sufficiently advanced for at least limited application within only a few years. It is complicated by the presence of some 50 unusual base fractions which derive primarily from the normal turnover of tRNA, by its reliance on expensive and highly specialized procedures, and by its probable requirement for prior knowledge of the nature of base damage induced by particular agents. The method is nevertheless likely to display great sensitivity and chemical diagnostic capabilities.

B. MEASUREMENT OF DAMAGE

Unscheduled DNA Synthesis (UDS) in Peripheral Lymphocytes

DNA that is damaged by radiation or chemicals can often be repaired by localized removal of the damage area and replacement with new nucleotides. If the new nucleotides are radioactive, the extent of repair can be measured [10, 11]. A number of authors have suggested the measurement of DNA repair, usually designated unscheduled DNA synthesis, as an indicator of exposure of chromosomes to mutagenic agents. As yet, this system has not been used to detect damage to persons exposed to mutagens. A report that the in vitro induction of unscheduled DNA synthesis in lymphocytes of normal persons is positively correlated with chromosomal aberrations in circulating lymphocytes suggests that unscheduled DNA synthesis may be associated with mutation, although it is difficult to predict the nature of the association [12].

In this procedure, venous blood is drawn and the lymphocytes are removed and cultured in the presence of hydroxyurea to inhibit normal (scheduled) DNA synthesis. Tritium-labeled thymidine is added to the culture: the only DNA synthesis that should occur results from the repair of single-strand gaps generated by the excision of damaged nucleotides. The extent of tritiated thymidine incorporated into these gaps provides a measure of unscheduled DNA repair synthesis (UDS). There have been few UDS studies on lymphocytes in vivo. Limited studies of normal human lymphocytes have indicated that sex, age, and blood pressure may affect both the background and chemically induced responses. There is no available information on individual variability (day-to-day, sampling time, diet, life-style, emotional attitude, etc.). Controlled studies are required to evaluate such factors for their impact on population monitoring. If they can be controlled, and if suitable control populations can be identified, UDS in peripheral lymphocytes could become a usable exposure monitoring technique within only a few years. Repair synthesis is comparable in human and animal tissues, as are the methods for its measurement, with the important proviso that for general human application the incorporation of radioactive precursors of DNA must be carried out in vitro after the tissues have been sampled. The method is necessarily indirect; uptake of radioactivity need not be specific for repair; and there can be false negatives due to toxic inhibition of repair. Following an acute exposure to a mutagen, repair synthesis is likely to be largely complete in a day or so.

Hemoglobin Alkylation

Measuring alkylated amino acids in hemoglobin has been proposed as a means of monitoring exposure to alkylating agents. This is far from a genetic event, but protein alkylation strongly implies the concurrent alkylation of nucleic acids, a potential first step in the production of mutations. In one method, hemoglobin from circulating red blood cells is extracted and analyzed for the presence of alkylated derivatives of histidine or cysteine. In another method, the loss of histidine or cysteine is measured as the ratio of these amino acids to nonalkylatable amino acids. These procedures have only been reported for mice injected with known mutagens, and on human red blood cells treated with mutagen in vitro (and in only two laboratories); there are no reports of their practical application to humans. All reported work has been on pooled hemoglobin samples, and the reported sensitivities of the methods are low. Before these techniques can be considered for routine monitoring, extensive validation studies would have to be performed to standardize protocols, measure reproducibility and the individual variability, and determine the sensitivity of the method in detecting alkylation by diverse mutagens. Hemoglobin alkylation is thus experimental in terms of its applicability to human monitoring.

The assessment of the degree of alkylation in man requires the development of nonradioactive methods using samples acquired with a minimum of risk to the individual.

The possibilities for using hemoglobin from red blood cells as a chemical dosimeter have been explored by Ehrenberg and coworkers in a series of experiments on mice using directly alkylating agents [13-15], as well as agents that need metabolic activation [14-16]. After treatment of the animals with the radiolabeled compounds, the degree of alkylation of *guanine-N*-7 of DNA and of cysteine-*S* and histidine-*N*-1 and -N-3 in proteins from different organs were determined parallel to the determination of alkylation of cysteine and histidine of hemoglobin. It was shown that for small, rapidly diffusing and sufficiently stable molecules, such as ethylene oxide (biologic mean-life, about 12 minutes [13-14]), and methyl methanesulfonate (biologic mean-life, about 40-50 minutes [15]), the erythrocyte dose is representative of doses of other organs, including the liver and the testes. For more unstable compounds, such as the reactive metabolites from vinyl chloride [17], and dimethylnitrosamine [14], the gonad doses were considerably lower than the erythrocyte doses.

The accumulation of alkylated groups in hemoglobin and the relatively large amounts of hemoglobin that may be isolated from one blood sample and analyzed, together with an application of sensitive analytic techniques, make it feasible to determine the small quantites of alkylated amino acids that may be formed as a consequence of exposure to genotoxic compounds in the environment.

Work in progress with the compound methyl bromide indicates that, due probably to the lipophilic character of this compound, the degree of alkylation of DNA is much smaller than expected from the reaction kinetic data, and that a "correction factor" should be introduced when estimating DNA-alkylation from hemoglobin data. Other factors that modify the alkylation pattern and factors that affect the biologic response include: steric factors, charge, bifunctionality, high reactivity, interactions with other compounds, and repair mechanisms.

Continued studies aimed at an evaluation of such factors and further development of the techniques to determine the degree of alkylation of hemoglobin should provide a basis for meaningful risk estimates for a larger number of mutagenic compounds [18-20].

Although this system is very agent-specific and requires additional development, it may ultimately prove useful where identity of the agent is known, such as in occupational exposures.

DNA Adducts

Many chemicals alter DNA bases, either degradatively or by adduction. DNA extracted from any readily obtained human tissue can be analyzed for the presence of chemically induced abnormal bases. Some products, such as 7-alkypurines involving small adducts (e.g., methyl or ethyl), are innocuous, but may serve as general indicators of DNA damage. Adducts at most other sites, and especially bulky adducts which interfere with subsequent DNA replication, are highly genotoxic unless efficiently repaired; and certain base alterations are directly mutagenic without a requirement for subsequent DNA replication. Except where noted, the following analytic methods are readily available in research laboratories, but will require several years to adapt to standardized screening with the concomitant development of a human data base.

Many altered bases trigger excision repair, which may be detected as a consequence of associated strand breakage or UDS (see above); however, repair mechanisms involving glycosylases and insertases have recently been discovered; these do not involve strand breakage and gap formation, and it is unclear what fraction of DNA damage is susceptible to this type of repair. Damages in uncleaved DNA may be detected either by the use of endonucleases which cleave at the sites of damage, generating breaks and gaps which can be detected as such, or by extensive (and preferably enzymatic) digestion of damaged DNA followed by high-resolution analyses for aberrant bases by fractionation techniques (e.g., paper, column, thin-layer and high-pressure liquid or gas chromatography) and identification techniques (e.g., mass spectrography) where amounts are exceptionally small. It should be noted that available DNA degradative methods may not always be suitable, and that radiolabeling to assist detection of rare products will generally be impossible in the case of human tissues.

DNA adducts have been measured in human cells and tissues exposed in culture, and are readily measured in tissues and sperm of laboratory animals [13]. Sensitivity, in such experiments, currently requires radioactive adducts, an asset that would not be available for general human use. Feasibility in the human is, therefore, uncertain but should improve, perhaps to the point of applicability as methods improve for chemical analysis of specific adducts [21]. Sperm would be prime test targets because of their genetic relevance, their availability, and the accessibility to adduct formation during their final preejaculatory weeks when repair is no longer present.

DNA Strand Breaks

Many chemical lesions in DNA can produce either single- or double-strand breaks, both directly or as a result of subsequent excision repair. Such damage can be measured in any readily sampled human tissue, including circulating white blood cells of all types, skin biopsies, and biopsies from more profoundly invasive procedures. A plethora of analytic methods is available, most of which are in many laboratories and are well standardized. Validation studies on animal models are in most cases reasonably well under way, but validation in humans and the development of a background data base will, again, require several more years. The viscosity of DNA is reduced by both double- and single-strand breaks, and can be measured by rotating cylinder viscometry with high sensitivity; however, that is a rather specialized technique. A much more widely available method is ultracentrifugation, which usually takes the form of sedimentation velocity (through gradients or not) or band sedimentation centrifugation. Appropriate manipulation of the method allows discrimination between single- and double-strand breaks, which may be useful because double-strand breaks more likely may be precursors of chromosomal mutations at low doses. In the special case of small circular DNA molecules, such as the genomes of mitochondria, equilibrium density gradient centrifugation in the presence of ethidium bromide is a particularly useful and sensitive assay for both types of breaks. Electron microscopy to characterize length distributions, particularly with the use of enzymes or other proteins which recognize single-strand breaks, is also useful but is rather specialized. A recent method, but one which is very sensitive and is already widely available, is gel electrophoretic determination of molecular weight distributions. Finally, several methods are available to differentiate DNA according to both strand length and presence of single-strand gaps in mainly double-stranded DNA (a consequence of single-strand breakage followed by enzymatic gap formation) by differential binding to membrane filters or columns of various types. Other methods which have been used in the past but are of insufficient sensitivity for human monitoring are ultraviolet spectrophotometry (including hyperchromic effects and decreases in melting temperature), light scattering, flow dichroism, and recognition of DNA termini by various proteins. A general limitation on the use of any of the above techniques is the ease with which breaks are introduced into DNA by just the sorts of manipulations which are required to isolate DNA from human cells.

C. MEASUREMENT OF SOMATIC CELL MUTATIONS

HPRT Specific Locus Test in Peripheral Lymphocytes

One of the most useful systems in the study of cell biology has been the hypoxanthine phosphoribosyltransferase (HPRT) locus, which is X-linked in mammals. Mutations to loss of activity of this enzyme cause resistance to the guanine analogs 8-azaguanine (AG) and 6-thioguanine (TG). Thus, wild-type HPRT$^+$ cells can be selected against by incorporation of one of these analogs. Conversely, HPRT$^+$ cells can be selected for (i.e., revertants from HPRT$^-$ cells) in the presence of HAT (hypoxanthine-aminopterin-thymidine) medium. It should be possible to select for HPRT$^-$ cells in normal HPRT$^+$ persons with one of the analogs; this was one of the first systems used to detect spontaneously occurring mutants in freshly cultured cells from humans [22, 23].

The frequency of TG-resistant cells has been reported to be on the order of 1×10^{-4} among peripheral blood lymphocytes of normal persons [24]. The frequency is generally higher among cancer patients under therapy with known mutagens. This system, therefore, offers the possibility of detecting somatic mutations through selection in lymphocyte cultures. Much has yet to be elucidated about the variables that influence the results. Nevertheless, the ability to measure mutation in somatic cells and to document the nature of the mutation makes this a promising system.

Hemoglobins

The red cells of an individual contain almost pure hemoglobin. In the human population there are many different heritable mutations that lead to individuals whose red blood cells contain variant hemoglobin. Some of these hemoglobins differ sufficiently from normal hemoglobin to produce monospecific antibodies. By attaching a fluorescent molecule to the monospecific antibodies against a certain variant hemoglobin, one should be able to localize the few red blood cells that contain this different hemoglobin.

The first successful variant hemoglobin system was developed with the sickle cell hemoglobin in humans [25]. In a normal human, the frequency of red blood cells that contain sickle cell hemoglobin is 10^{-7}. The mutation from hemoglobin A (HbA) to hemoglobin S (HbS) is a specific base pair substitution and may not occur with many mutagens [26]. It is, therefore, very important to expand the type of mutations that are scored. Monospecific antibodies have now been produced to hemoglobin-C and -E, both base pair substitutions; to hemoglobin Wayne and Cranston, both frameshift mutations, and to hemoglobin Constant Spring, which is a terminator mutation.

The frequencies of the mutant cells are so low that handscreening for the mutant cells is not feasible, even for a modest screening program. Development of automatic counting systems is in progress. The reaction of the monospecific antibody with the variant cell is not proof that this cell originated by mutation, since unknown epigenetic changes may mimic the mutant. Therefore, the genetic origin of the mutant has to be established, which can be done by isolating enough mutant cells to obtain biochemical proof of the mutant protein.

Theoretically, this technique is as genetically sound as any to be used as a general monitoring system for the human population; but in summary, several technical and theoretic developments remain to be accomplished.

1. Establish the mutational nature of variant cells;
2. Develop the automated counting systems;
3. Validate the response in humans who accidentally or therapeutically have been exposed to known mutagens;
4. Develop animal modeling system for interpretation of the data;
5. Produce monoclonal high affinity antibodies to the various variant hemoglobins.

D. MEASUREMENT OF GERM CELL MUTATIONS

LDH-X Variants in Human Sperm

Most systems for detecting heritable mutations in mammals require the study of offspring of the exposed individuals. Several thousand offspring must be screened to obtain any meaningful data. One alternative to monitoring progeny of exposed individuals is being developed. It is the direct screening of sperm from exposed individuals for point mutations through the use of an appropriate marker protein. The advantage of such a single cell screening system would be that each cell, rather than each individual, could be scored for a mutational event. Such a system could be used to a) monitor the human population for genetic damage caused by exposure, and b) screen chemicals for their mutagenicity.

An immunologic system, based upon the use of antibodies against lactate dehydrogenase-X (LDH-X), appears promising. An antibody population has been prepared that binds rat LDH-X but not mouse LDH-X [27-31]. In a sandwich fluorescent antibody technique, this antibody stains rat sperm, whereas mouse sperm remains unstained. If an LDH-X gene undergoes mutation such that the amino acid sequence of the enzyme is altered so that it will bind the anti-rat LDH-X antibody, sperm containing such mutant molecules can be identified by immunofluorescent stain. From DBA/2 control mice, 72 fluorescent sperm were found among 167×10^6 cells, giving a spontaneous frequency of presumptive mutations of 0.43×10^{-6}. The frequency of these events increases linearly upon treatment of the mice with increasing dosage of procarbazine [32]. The experiment with procarbazine was repeated and a similar dose vs response relationship was obtained. Experiments using mitomycin-C and ethyl nitrosourea (ENU) are in progress to obtain dose vs response relationships.

Amino acid sequence and antigenic site analyses of the LDH-X from mouse, rat, and human are required for better characterization of the presumptive mutational events. Until this information is available, it remains unclear just what types of changes are being detected and how they relate to modification of DNA.

Antibodies are being made that will detect similar mutational events in human sperm.

Although antibodies required for the mutation study have been produced, and very encouraging results are being obtained in terms of dose vs response relationship, it seems impractical to think that this system can be applied to human mutation monitoring purposes for perhaps another two years.

E. MEASUREMENT OF GENE MUTATIONS IN F_1 PROGENY

Reproductive Potential

A commonly used test in experimental animals is the dominant lethal, generally assumed to detect the induction of chromosomally abnormal sperm. There are reports of loss of fertility on exposure of human males to various chemicals. It is difficult to attribute such effects to a genetic event rather than a cellular effect. An increase in genetically defective sperm, detected by diminished fertility, would require a very large and carefully controlled study. The use of birth control and the changing social patterns of family size virtually rule out evidence on fertility as useful in monitoring mutagenesis.

Phenotypic Effects

Much thought has been directed to the possibility of selecting sentinel phenotypes that result, at least in part, from mutation and that can be used to measure increases in mutation rate. Only a small number of single gene traits have been identified that would be especially useful for this purpose. However, since the frequency of mutation is so low, a very large population is necessary to estimate the frequency of new mutants or to detect a change in that frequency. This could be solved in part if complete and readily accessible health records existed for large political units. Newcombe [33] has studied the problem from the point of view of computer linkage of public records.

One shortcoming of this approach is that the time between the mutation and the conception might be long, making it very difficult to relate an increase in inherited defect to the responsible agent. On the positive side is the fact that clinical defects are part of the concern for chemical mutagens, and the relevance to human risk and health load is direct.

Electrophoretic Variants in Blood Serum and Erythrocyte Proteins

In recent years, it has become possible to base the study of point mutation in man (and other animals) on changes in defined proteins. This has the advantage over the use of "sentinel phenotypes" in that the number of useful markers is potentially much larger, and numerous biochemical indicators can all be examined on the basis of a single blood sample; whereas a full evaluation of the relatively few (15-20) "sentinel phenotypes" requires repeated examinations of the cohort of children under consideration.

The technique of choice at the present is one-dimensional electrophoresis, using starch or polyacrylamide gel as the supporting medium. At least 35 different proteins of the blood serum and erythrocyte are suitable for accurate screening for variants by this technique (Table 2). Recently, this technique has been applied to the study of the genetic effects of ionizing radiation from atomic bombs [34]. Since only about 1 in 7 biochemical variants of these proteins is detectable by electrophoresis, only a minority of biochemical variants can be detected by this approach. Cost wise, the expenditure per locus screened is in the same range as the approach employing "sentinel phenotypes," although a precise comparison is

Table 2. List of proteins currently being screened by electrophoresis in the Department of Human Genetics in Ann Arbor for the occurrence of mutation.

Protein	Symbol	E. C. No.
Albumin	ALB	
Ceruloplasmin	CRPL	
Haptoglobin	HP	
Transferrin	TF	
Acid phosphatase	ACP1	3.1.3.2
Adenosine deaminase	ADA	3.5.4.4
Adenylate kinase-1	AK1	2.7.4.3
Carbonic anhydrase-1	CA1	4.2.1.1
Carbonic anhydrase-2	CA2	4.2.1.1
Esterase A	ESA	3.1.1.1
Esterase B	ESB	3.1.1.1
Esterase D	ESD	3.1.1.1
Galactose-1-phosphate uridylytransferase	GALT	2.7.7.10
Glucose phosphate isomerase	GPI	5.3.1.9
Hemoglobin α	HG α	
Hemoglobin β	HG β	
Hemoglobin δ	HG δ	
Isocitrate dehydrogenase	ICDS	1.1.1.42
Lactate dehydrogenase A	LDHA	1.1.1.42
Lactate dehydrogenase B	LDHB	1.1.1.42
Malate dehydrogenase	MDH	1.1.1.37
Nucleoside phosphorylase	NP	2.4.2.1
Peptidase A	PEPA	3.4.1.1
Peptidase B	PEPB	3.4.1.1
Peptidase C	PEPC	3.4.1.1
Peptidase D	PEPD	3.4.1.1
Phosphoglucomutase-1	PGM1	2.7.5.1
Phosphoglucomutase-2	PGM2	2.7.5.1
Phosphogluconate dehydrogenase	6PGD	1.1.1.44
Triosephosphate isomerase	TPI	5.3.1.1
Glucose-6-phosphate dehydrogenase	G6PD	1.1.1.49
Glutamic oxaloacetic transaminase, soluble	GOTS	2.6.1.1
Hexokinase-1	HK1	2.7.1.1
Hexokinase-2	HK2	2.7.1.1
Phosphoglycerate kinase	PGK	2.7.2.3
Uroporphyrinogen I synthase	UPS	4.3.1.8

impossible because it is neither clear how many loci are subject to mutation resulting in a specific "sentinel phenotype" nor what proportion of mutation at those loci associated with "sentinel phenotypes" is detected by the morphologic approach.

Techniques are becoming available for screening human enzymes for variants resulting in extreme loss of enzyme activity, and in alterations in enzymatic thermostability. The former, conveniently studied with the use of the centrifugal fast analyzer [35, 36], has been found in a study of a series of 10 enzymes to have a frequency about 3 times as great as electrophoretic variants [37]. The latter, whose detection is more time consuming than the detection of nulls, is also about 3 times as frequent as electrophoretic variants [37]. The "efficiency" of indicators of this type for the study of mutation, as contrasted with electrophoretic variants, will be determined by the relative frequency of newly arisen mutants among the variants, on which point there is as yet no information.

A technology just becoming available involves the use of 2-dimensional polyacrylamide gel electrophoresis, in which the first dimension is determined by isoelectric focusing of a disk gel and the second dimension, obtained by applying the disk gel to a polyacrylamide slab, results from standard electrophoresis [35, 38-40]. Application of this technique to blood serum, or an erythrocyte or lymphocyte lysate, results in the visualization of as many as 1000 protein moieties when a sensitive silver stain is employed. It is not yet clear how many of the proteins visualized will be sufficiently reproducible (and have the other necessary characteristics) to be useful in studies of mutagenesis, but the number should not be less than several hundred. Inasmuch as preliminary studies have suggested a high degree of constancy, it would appear that much of the reading of these gels can utilize computer programs specifically developed for the analysis of these images, with operator intervention into the analytic process whenever a protein candidate for mutation is encountered. (The logical problems involved in developing the necessary programs are much simpler than in automated karyotyping.) The actual verification of a suspect protein as a mutant will require a variety of supplementary techniques, such as the use of monospecific antibodies to isolate the protein and high-pressure liquid chromatography and protease digests to characterize the protein.

Finally, one must consider the study of induced mutation at the nucleotide level, using restriction-site endonucleases to scan for alterations in short nucleotide sequences or gains or losses of DNA sequences in excess of 100 nucleotides. While this approach is currently not as efficient as electrophoresis, especially of the 2-dimensional type, the technology is advancing so rapidly that it would be presumptive to foreclose this as an option. A disadvantage of this technology is that, in contrast to the study of proteins whose abnormalities can often be directly related to disease processes, the bulk of the mutations detected by this approach will not involve translated DNA, and so their biomedical significance will be unclear.

The entire biochemical approach to the study of germinal mutation is in a state of flux and rapid evolution. There is no doubt it is a viable technology, in both the human and experimental setting [41, 42]. How it will compare in cost to sentinel phenotypes is not clear. Much depends on the circumstances under which it is pursued. For instance, in West Germany the search for mutant hemoglobins using the blood stain submitted for the diagnosis of phenylketonuria is quite inexpensive [43]. A particular advantage of the 2-dimensional approach is that in theory, by combining information available from lymphocytes, erythrocytes, serum, hair follicles, and saliva, one could score as many as 1000 different proteins for mutants, a possibility which outstrips any other in the amount of information to be contributed by a single child born to parents exposed to a potential mutagen.

The Implementation of These Guidelines

James V. Neel, MD
Department of Human Genetics
University of Michigan Medical School
Ann Arbor, Michigan 48109

My assigned responsibility is to attempt to summarize what has been a very intense two days, with particular reference to defining the interrelationships between the three sets of guidelines which have been developed. In the usual sequence, one would follow that sort of summary with some comments about the scientific and financial demands of these protocols. It occurred to me, however, that it would be worthwhile to reverse the usual order of events, and open my remarks with a discussion of the costs of *not* developing and then pursuing the implementation of a proper protocol to evaluate the impact of current exposures to potential mutagenic and reproductive hazards.

THE COST OF INADEQUATE EVALUATIONS OF POTENTIAL MUTAGENS AND TERATOGENS

For more than 50 years, students of genetics and teratogenesis have been writing voluminously concerning the effects of radiation and chemical agents in experimental systems, and alluding to the implications for humans. The public, especially during the last decade, has been attentive. The resulting public concerns have been manifested in two very concrete fashions. On the one hand, it has become mandatory to screen new pesticides, herbicides, pharmaceuticals, etc. for mutagenicity and teratogenicity while they are still under development, with the objective of intercepting those which appear particularly hazardous. On the other hand, on the basis primarily of observations on non-human model systems, an effort has been made to set permissible limits to exposures to a variety of man-made agents in the environment. Historically, both of these developments have their roots in an effort to screen the public from carcinogens, but as the extensive overlap between mutagens and carcinogens has emerged, increasingly the two types of screening have become synonymous, a point to be returned to later.

So far as I am aware, no responsible person wishes to quarrel with the thrust of either of these developments. Unfortunately, however, as scientists and administrators alike seem to agree, there is a wide band of uncertainty in our efforts to screen out mutagens and/or extrapolate from an experimental setting to effects on human populations. These uncertainties permit persons of good intent to develop quite different viewpoints; a situation abetted by conflicts in the interpretation of such sets of human data as are available. We are not talking about differences to the right of the decimal place, but about an order-of-magnitude difference in the positions responsible parties have adopted. The uncertainties are such that the National Science Foundation, in its first Congressionally mandated effort to provide the Congress with a 5-year projection of the nation's research needs, targeted improving the science and technology base for risk assessment as one of its 5 high priority items [1]. A more concrete manifestation of these same concerns is the recent Toxic Substances Control Act (15 USC 2601), requiring EPA to formulate standards for the development of test data relating to human genetic effects.

The humanitarian aspects of a proper appraisal of the risks in question are obvious. In this connection, I assume familiarity on the part of the audience with the voluminous committee and other reviews of the impact of spontaneous mutation on the health of a population and the consequences of an increased mutation rate [2-9].

Not quite so obvious as the humanitarian have been the financial aspects of the appraisal problems. Unjustifiably stringent regulations upon industry will place our nation at a competitive disadvantage among industrialized countries, at a time when it is clear that even at best we face some difficult years. The pronouncements of the new Administration suggest a concern that regulations concerning environmental pollution have become overly stringent, but every fresh revelation of some of the unnecessarily careless waste disposal practices of the past only further stiffens public concern. The longer the necessary resolution of the strong differences of opinion which exist concerning this matter is drawn out, the greater the expense to us all. I am sure I do not have to emphasize what failure to reach a clear position regarding nuclear energy has cost this country. Furthermore, continuing uncertainties will encourage further individual and class-action legal initiatives for damages which already cumulate to a very large sum, initiatives where the basis for a just settlement is very obscure. Although most of these actions now relate to carcinogens, I suspect that during the next decade the suspicion of mutagenic and teratogenic damage will come increasingly to the fore. There is ample legal precedent for awarding damages on the presumption of injury; in the absence of sound data — in this case, probabilities of genetic or teratogenic damage — the courts, which *must* reach a position, will be seriously handicapped in the discharge of their responsibilities. Understanding the possible carcinogenic, mutagenic, and teratogenic implications of the many environmental agents to which we are exposed is not an academic exercise but one of the two or three most important challenges to biomedicine in the next decade. Decisions entailing billions of dollars are involved. In this connection, I must once again chide many of my genetic colleagues for talking big but thinking small. We have spoken copiously of the possible risk to future generations of environmental contaminants, but, in my opinion, thus far failed either to formulate or request funds to pursue proper epidemiologic studies. I shall speak to the one exception to that statement later. Hopefully, this Conference will be seen in retrospect as the occasion when geneticists, stimulated by the ineptitude with which the issues created by the Love Canal episode were pursued, first laid out to Government what had to be done in the nation's interest.

COORDINATING OUR THREE SETS OF GUIDELINES

The three sets of guidelines with which we have been presented are each the product of much thought and experience, and it is certainly not my intention to critique them. Rather, I would like to speak to the issue of their coordination in any real-life situation. By and large, the guidelines of Panel I deal with studies of *somatic* effects which, if positive, create the *presumption* of transmitted genetic damage but by no means prove it, much less permitting an estimate of its magnitude. The guidelines of Panel II deal in part with the detection of both mutagenic and teratogenic influences, and, if the population is still exposed to the agent(s) in question at the time of study, a positive finding with respect to some indicators, such as congenital defects, would not necessarily permit a decision as to which kind of influence is involved. In addition, the guidelines of Panels II and also of III deal with a mixture of somatic and true genetic end points, using the word 'true' in the sense of that which can be transmitted across generations. Now, the costs of the studies of such somatic cell end points as chromosomal damage, SCEs, and frequency of mutant erythrocytes or leukocytes are far less than studies of such indices of transmitted genetic damage as certain types of congenital defects, chromosomal abnormalities, or biochemical traits. It will be administratively tempting to implement the former but not the latter. This would be a tragic mistake. *At present, we have no sound basis for extrapolating from somatic cell end points to genetic effects.* Perhaps the outstanding example of this stems from the studies in Hiroshima and Nagasaki of atomic bomb survivors and their children. The demonstration of chromosomal damage in survivors [10-12] as well as increased rates for a variety of malignancies (reviewed in reference [13]) has been clear and unequivocal. However, the demonstration of genetic damage in their children has been much more equivocal, as we shall see later. It is essential that as the monitoring of populations is initiated, we must build the intellectual bridges, the conversion factors, between the various kinds of studies envisioned in the three sets of guidelines, and it has to be done with human data.

In the face of the labor involved in building these bridges, there are sometimes suggestions that one use a mixture of human epidemiologic and non-human experimental data in setting risks to human populations. If there were any lingering doubts about the absolute requirement for human data all the way, I would suggest they should be dissipated by our recent analysis of the accumulated data concerning children born to survivors of the atomic bombings of Hiroshima and Nagasaki [14]. This analysis differs from its predecessors in the use it makes of individualized estimates of gonadal dosage, only available since 1978, and the incorporation of recently acquired sets of data. Although our colleagues and ourselves have at one time or another attempted to collect data on all the aspects of pregnancy termination mentioned by Panel II, for this new analysis we have pursued the more qualitative and, in our opinion, reliable of the available indicators, namely, 1) untoward pregnancy outcomes (stillbirth, congenital defect, and/or death during the first postnatal week), 2) death among live-born infants up to a mean age of 17, 3) sex chromosome aneuploidy, and 4) mutation resulting in electrophoretic variants of a battery of 28 proteins. For each indicator, the difference between the children of exposed and unexposed is of a nature to suggest genetic damage to the parents, but none of the differences begins to approach significance. On the thesis that the radiation exposure did in fact have a genetic effect, a thesis justified by a great body of experimental data, we have undertaken to estimate the genetic "doubling dose" for this type of radiation exposure, i.e., the amount of radiation producing the same frequency of mutation as occurs spontaneously. This estimate, of some 160 *rem,* is approximately 4 times greater than the estimate derived from the specific locus test system in the mouse, which latter estimate has until now largely guided our thinking (see reviews cited earlier). Incidentally, with reference to the guidelines of Panel II, we no longer employ changes in the sex ratio in the evaluation of a genetic effect, because of the difficulty in establishing *a priori* expectations in view of the possible induction of sex chromosome aneuploids and the potential role of the Lyonization phenomenon in obscuring the expression of sex-linked mutations in the human female.

I have heard a lot of comments the past 2 days, to the effect that we do not know how to monitor human populations for transmitted genetic damage. Those comments manage to overlook the fact that over the past 35 years, under the aegis of the NAS, financed by the (now) DoE, a protocol has been developed, finally yielding the data I have just summarized. It is not perfect, but neither is it pie-in-the-sky. Unfortunately, it is so difficult and laborious to implement that I sense a real reluctance to face up to what it takes. The sooner we get cracking on what we can do right now, the sooner we meet the moral responsibility we have brought upon ourselves by our frequent presentations to the public of the potential genetic dangers with which they are surrounded.

Should our analysis of the Japanese study stand — and you may be sure it is being subjected to very critical review at present — then it will forever document the difficulties in extrapolating with any great accuracy from contrived laboratory situations to effects in heterogeneous human populations. Lest there be misunderstanding, I have been and remain a strong proponent of the usefulness of animal experimentation in establishing the broad outlines of a situation, but believe we absolutely must have human data for the necessary fine tuning. Furthermore, should a positive finding emerge from a survey of human populations, it would and should be a strong stimulus to experimental programs designed to clarify the nature of the agents involved.

Having now stressed the need for establishing, insofar as possible, the interconversions between the various end points covered by the guidelines, let me emphasize that once the basis for extrapolating from somatic to genetic effects in humans has been established, then the more costly and elaborate studies of transmitted genetic damage may be no longer necessary, or necessary only under particular circumstances. But without the somatic-genetic linkage, we will never know the genetic significance of an increase in visible chromosome damage or SCEs in somatic cells, or of mutant erythrocytes, or of abnormally-shaped sperm. This salient truth is often lost sight of. For instance, I note that Brusick [15], in his recent generally excellent book entitled "Principles of Genetic Toxicology," in the chapter on Environmental and Human Monitoring, says nothing about the study of children born to individuals thought to be at risk of a genetic insult!

Incidentally, the one point on which I would be critical of Guidelines I and II is failure to emphasize sufficiently the need for establishing decay curves following a mutagenic insult, for such phenomena as gross chromosomal damage, SCE frequencies, or sperm abnormalities. The populations which will come under study will be at varying intervals from the genetic insult, and the ability to extrapolate from somatic genetic end points to germinal requires intimate knowledge of that decay curve.

COMMENTS ON THE DESIGN OF FIELD STUDIES

There are in principle just two designs for field studies. On the one hand, one can establish well-defined samples ("census tracts") of the general population which are then continuously monitored for changing mutation rates, most conveniently on the basis of appropriate examination of newborn infants and their parents. Pilot studies on how this best can be done, employing various biochemical markers of mutation, are being performed in Michigan by Neel et al [16], and in West Germany by Vogel and Altland [17]. A basic problem with the prospective census tract approach in any highly industrialized country such as the United States, Japan, or West Germany is that even if no upward trend in mutation rates is detected in the future, it can be maintained that an undesirable increase in the mutation rate has *already* occurred, which this approach might serve to legitimize. On the other hand, one can undertake a "worst cases" analysis, in which one identifies groups of individuals at presumed high risk to a mutagen and pursues appropriate studies on their children, plus the necessary control studies. The chief experience to date with this approach stems from the joint United States-Japan follow-up studies in Hiroshima and Nagasaki, to which I have already alluded. Dr. Miller has spoken in this conference primarily to the problems in identifying populations at high risk of chemical exposures within the United States. With respect to radiation exposures, a recently completed study commissioned by the U.S. Nuclear Regulatory Commission [18] suggests the most appropriate groups within the United States to be workers in health services, nuclear power plants, Department of Energy-supported facilities or nuclear shipyards, and people who received routine pre- and postnatal radiologic examinations. In addition, three groups receiving special environmental exposures were identified; namely, people exposed to fallout from the Nevada Test Site, plutonium from the Rocky Flats Plant in Colorado, or radon from phosphate-rich lands in Florida. I need not comment on how critical the identification of suitable control groups becomes.

The exact magnitude of the study which must be envisioned depends entirely on the magnitude of the anticipated effects. Here of course is where controversy intervenes. On the basis of our follow-up studies in Hiroshima and Nagaski, as well as the experimental data, I do not believe that current U.S. exposures to mutagens and teratogens, even in high-risk groups, have had a substantial impact on the end points we have been discussing. We are thus looking for small effects, usually in as large a sample as can be assembled. This requires the utmost sophistication in epidemiologic design, a sophistication which some feel has been lacking thus far in many of the federally funded research projects in this area (see, for example, Committee on DoE Research [19] or the voluminous recent exchanges re the Love Canal fiasco). Let us return briefly to this matter of determining the necessary sample size for a study, so well discussed by Panel II. Let us agree that any study should certainly not fail to detect an increase in mutation rates of 50% or greater. Elsewhere — as an illustrative calculation — I have suggested that, given the restriction of a Type I error of 0.05 and a Type II error of 0.20, and employing protein phenotypes, for which the assumed baseline average mutation rate was 10^{-5}/locus/generation, it would require 2 samples of some 7,000,000 observations each to detect a 50% increase in mutation rates [20, 21]. Vogel has presented similar estimates [17, 22]. Of course the number of children contributing to that sample depends on the number of bits of information per child. If both parents are exposed and there are 50 indicators per child, the sample size is 70,000 children. If with the new 2-dimensional electrophoretic technologies one can reach 500 observations per child, then only 7,000 children will result in 7,000,000 observations. If the indicator were a gross chromosomal defect, which for the calculation can be assumed to have a mutational origin of approximately 4 x 10^{-3} among conceptuses reaching the 20th week of gestation (E.

Hook, personal communication), then the 2 sample sizes are approximately 19,000. Now the numbers apply to people. In either case, the numbers decline rapidly as the magnitude of the expected differences increases.

These are formidable numbers. They can most conveniently be obtained in studies of "census tracts," if these are made large enough; but few geneticists feel such populations are at risk of 50% increases in mutation rates in the years ahead. For the "high-risk" populations, one might be satisfied to detect within the previously mentioned statistical limits, an increase of at least 100%. Now the necessary numbers will be less than half the preceding figures but even these numbers are difficult to assemble from high-risk populations, since the number of available children from any one group is, fortunately, relatively small from the genetic standpoint. One way to increase the numbers is to make the studies retrospective as well as prospective. Retrospective studies must be conducted with exquisite care that the indicators not carry a poorly defined increased risk of early death which always complicates documentation of an effect. Under these circumstances the most suitable, the "cleanest" indicators of *transmitted* genetic damage are such subclasses of chromosomal abnormalities as sex chromosome aneuploids and reciprocal translocations, and the biochemical traits, some of which (the "nulls") while usually associated with serious disease when homozygous, do not seem to be deleterious in the heterozygous state in which they would present as mutations.

While in principle such data can be collected (and are being collected) at the present time, I would suggest that the prospects for methodologic improvements are excellent, and funding designed to make the collection of cytologic and biochemical data more efficient would be well justified. I refer especially to the development of the 2-dimensional polyacrylamide gel electrophoretic techniques which permit us to visualize 500 to 1000 proteins from readily accessible biologic samples. Coupled with automated image analysis and the power of monoclonal antibodies, high-pressure liquid chromatography, and rapid protein sequencing techniques, this technology has already ushered in a new era in our ability to identify and characterize protein variants in man — and protein variants are what we are all about. In this connection we should not overlook the possibility that recent developments in the ability to characterize variation in DNA may soon permit us to study mutation at this level, but, to understand the impact of the phenomena being measured on the proteins through which genetic damage is manifested, such studies, at least at the outset, need to be correlated with appropriate studies of selected proteins. By now it should be clear I cannot subscribe to the generally negative tone of the BEIR III report (1980) concerning the prospects for human data, as reflected in the following statement:

> "Few human data are — or are ever likely to be — available in the variety and depth needed to give us direct and simple answers to our questions. Hence, to estimate human genetic risks, we must find ways to apply information from other sources." (p. 94)

What other sources? I believe that the Genetics Sub-committee was simply out of touch with current technical developments.

There is an important aspect of the design of field studies which must not go unnoticed. This is the issue of sponsorship and direction, which is really the issue of credibility. Very simply stated, many advocacy groups have lost confidence in the objectivity of any government-sponsored study. I strongly urge that the implementation of the guidelines we are discussing demands the creation of a "blue ribbon" advisory committee, whose membership will include government officials and investigators, university professors, and representatives of industry and public interest groups. The task of the chairman of such a heterogeneous group will be difficult, but only under these circumstances will there be public acceptance of any findings. I do not mean to suggest such a committee simply for public display; it must have the expertise to pass judgment on the final design of the necessary epidemiologic studies. It is unlikely that *any* study will ever encompass all the possibilities in these protocols; there are some difficult choices to be made in the implementation of these various suggestions.

COMMENTS ON THE COST OF PROPER STUDIES

Although budgeting for various aspects of these guidelines is not part of the charge of this group, I believe it is incumbent upon us to provide approximate estimates. The costs of any proper study fall under 3 categories: front-end (collection) costs, laboratory costs, and data management costs. The front-end costs of any "census tract" approach are small, if one can use obstetric services as the focal point of the study with the opportunity they present for an in-hospital evaluation of the child, and the collection of a blood sample from its parents and itself. The front-end costs of a "worst cases" approach, which involves tracing persons with a mutagenic/teratogenic exposure, are substantially higher but presumably would be shared with an effort to evaluate the somatic effects of some particular carcinogen-mutagen, and would be a minor aspect of that effort. The laboratory costs depend of course on the end points. The costs of studies yielding the necessary sample size with respect to SCEs, chromosome damage, or in vivo somatic cell mutations are well within the bounds of funded research projects. So are the data management aspects of the undertaking. Larger sums of money are involved in the search in children for chromosomal or biochemical mutations. On the basis of the experience in Japan plus developments in laboratory technology which I believe to be imminent, I would set the laboratory costs of chromosomal or biochemical studies yielding the numbers cited earlier at 15 to 25 million dollars. The cost of the chromosomal studies is highly influenced by the degree of resolution one seeks — it will cost twice as much to do the kind of chromosomal "banding" studies which will facilitate the detection of small chromosomal lesions as to do studies directed simply towards the detection of aneuploidy. These costs are a fraction of what is spent each year in testing chemicals for carcinogenicity. Incidentally, it would seem of the utmost importance that from the outset, a feature of the research design be an effort to evaluate the cost-effectiveness of the component parts of any project.

SOME STATISTICAL CONSIDERATIONS

Concern is often expressed that even a very large study will be negative, in the sense of not yielding "statistically significant" results, and that this will create the presumption of no genetic effect where in fact one exists. In my opinion this concern is based on failure to understand the strategy of monitoring. There is no such thing as a negative study. In the first place, given present concerns, any substantial contribution to the available data is worthwhile. While proving the absence of any effect whatsoever is never practical, surely under present circumstances it is better to have some data on United States populations to point to than no data. Furthermore, the findings of the monitoring programs, even if they fail to demonstrate statistically significant effects, can always be used to set upper limits at specified confidence levels on the magnitude of a true effect which may have gone undetected in the statistical sense. Finally, now, if one accepts the presumption that there was a teratogenic-genetic effect, as for example we did in the Japan study, then one can always, taking the findings at face value, determine what they suggest regarding the exposure(s) necessary to double the end point for the phenomena in question, even in the absence of statistical significance.

The greatest statistical problem in a large monitoring program will be false-positive findings. This issue is well treated in Guidelines II, but is important and I believe it deserves reiteration. Let us assume that funding is available to do detailed studies on some 4 populations which appear to have had an unusual exposure to a mutagenic/teratogenic agent. Consider that within each of the 4 relatively high-risk populations, the parents are examined for the frequency of chromosome damage and SCEs, and their children for congenital defects and chromosomal and biochemical mutations. In this 4 x 5 matrix, by chance alone there should be one "significant" finding. Any use of this apparent "finding" will result in a major overstatement of the magnitude of the effect (cf. [23]). It must be clearly agreed from the outset that in this example, or a comparable situation, opinions concerning damage will be based on the totality of the data. The statistical methodology for dealing with this situation has recently received considerable attention in the context of seeking associations between histocompatibility antigens and disease states. Here, too, one does many tests in many populations. A rough rule-of-thumb procedure for the evaluation of a single test is to multiply the probability of exceeding the test criterion by the number of separate tests of hypothesis executed [24,25]. For instance, if 5 indicators have been examined in 4 populations, and the result is 19 observations for which the probability is greater than 0.05 but one for which the probability is 0.005, the "corrected value" for this latter is 0.10, and one would not conclude that there was an effect. A more sophisticated, multivariate approach has been described by Smouse [26].

THE COORDINATION OF STUDIES ON CARCINOGENESIS AND MUTAGENESIS

Epidemiologic studies of malignancy rates and life span in workers exposed to radiation in DoE facilities, nuclear shipyard workers, and uranium miners are already in progress, and more such studies are to be anticipated. It would seem only logical — and a considerable economy — that the genetic guidelines we have been discussing should first be implemented in these groups. But logical though this development would seem to be, it may need a little encouragement. That encouragement should come from the realization that this is not just a marriage of convenience but that, given the mutagen-carcinogen axis, detection of an increased germinal mutation rate today might be an advance warning of an increase in malignancy rates 10-20 years hence. The correctness of the obverse is more debatable. In this connection, one of the prime suspect groups from the standpoint of chemical mutagenesis may be 2-pack-a-day cigarette smokers. The consequences in terms of malignancy are well known, as is the mutagenic potential of their urine in the Ames test [27]. However, in the present state of knowledge it can be argued that most of the mutagenic potential of smoking is absorbed by the pulmonary tissues, with little of the mutagen reaching the gonads. Surely the study of this group should have high priority in efforts to understand the mutagenesis-carcinogenesis axis.

THE INTERNATIONAL SCENE

The guidelines developed at this meeting offer a particularly appropriate agenda for international cooperation. The current international interest has already been recognized by the World Health Organization through three Expert Consultations, held in 1978, 1979, and 1980 (see also references [28, 29]). Special groups at relatively high risk of a mutagenic exposure are scattered around the world. The best known of these is, of course, the children born to the survivors of the atomic bombings, on whom collaborative U.S.-Japanese studies have been in progress some 34 years; but there are such other lesser-known groups as the children born to Japanese engaged in the wartime manufacture of sulphur mustard gas [30], children whose parents were exposed to relatively high levels of arsenic in consequence of smelting operations in northern Sweden [31], children born to persons exposed to dioxin in the Seveso accident in Italy [32], or children born to Hungarians who have unsuccessfuly attempted suicide with insecticides or pesticides [33].

Few countries in which such populations occur will be in a position to undertake a complete protocol. It will be important that any partial protocol be undertaken in such a fashion that the results of studies in different countries be comparable. Furthermore, since the smaller countries are more apt to undertake studies which yield presumptive evidence of genetic damage, such as of chromosomal breaks and increased SCE frequencies, it is all the more incumbent on a country with the resources of the United States to undertake the studies on transmitted damage which render the other studies intelligible.

NO EASY WAYS OUT

The guidelines we have assembled these past 2 days offer no quick solution, no cheap litmus paper which an anxious public and a harried government can dip into our gene pool and get an immediate answer. The evaluation of the genetic and teratogenic implications of environmental and occupational exposures is surely one of the most complex and intensely practical challenges of our times. I hope I have made it clear that the reasons for monitoring are as much sociopolitical as scientific. Fortunately, the knowledge and technologies are at hand for an order-of-magnitude improvement in the ability of geneticists to deal with this problem, as compared with only a few decades ago. The next move is up to society, which alone, *properly informed,* can set the priorities which will result in the application of these guidelines.

Pollutants and Children: Lessons from Case Histories

Robert W. Miller, MD
Chief, National Cancer Institute-NIH, Clinical Epidemiology Branch
Bethesda, Maryland 20205

From case histories of environmental disasters we can draw lessons about what needs to be done clinically, epidemiologically and experimentally, (usually in that order). Lessons can also be learned from these case histories about public reaction and politics, but I will leave this subject to specialists.

CASE HISTORIES

Dibromochloropropane: Five workers at a factory in California had been unable to father children. Their physicians discounted the possibility that exposures at work might be responsible. The men took their own semen specimens to a clinical laboratory for study. The laboratory declined to give the results (sterility) to the men, but agreed to give them to a scientist who worked with both the industry and the unions involved [1]. A survey of workers in the U.S. and Israel revealed a substantial problem regarding spermatogenesis [2].

Kepone: Workers at an insecticide factory in Hopewell, Virginia, developed severe neurologic disability. Again, their physicians did not pursue the question of a work-related exposure. Finally, a Taiwanese-born cardiologist thought enough of the possibility to contact the USPHS Center for Disease Control directly, instead of through his state health department, as is usually required. In a fortuitous lapse of protocol Dr. Renate D. Kimbrough's laboratory agreed to study a blood specimen. It revealed chlordecone (the formal name for kepone) in high concentration. Study of the workers revealed that some were also sterile. Study of their wives and children revealed that 30 of 32 had the chemical in their blood, tracked home on the workers' clothing [3]. Study of the James River revealed contamination of fish that caused the river to be closed as a source of seafood.

Lead: In the early 1930s an epidemic of lead poisoning was observed among children from an economically depressed area in Baltimore. An intern, Dr. Miriam E. Brailey, went to the area to seek the source of the lead. She had no success until a bystander, Melrose Easter, whose "breath was strong with whisky" said he thought burning battery casings was to blame, for "the smell was bad, even made the food taste bad" [4]. In that household, the fumes were leaden enough to affect not only the child, but also the mother.

In 1974, a physician practicing near Kellogg, Idaho, wondered if two young sibs with abdominal pain, diarrhea, and otitis media might have lead poisoning because of the proximity of their home to a lead smelter. He obtained blood samples and found the lead levels were elevated. The CDC promptly screened other children in the neighborhood and found an epidemic of elevated levels [5]. Another episode at El Paso, Texas, was similarly studied [6]. A search was then made for heavy metal absorption among children living near other smelters throughout the nation. Lead was found to be an environmental problem near Herculaneum, Missouri; arsenic near copper smelters in Tacoma, Washington, and Anaconda, Montana; and cadmium near a zinc smelter in Bartlesville, Oklahoma [7].

Elsewhere, as in Raleigh, North Carolina [8], women who worked at a battery factory wore their clothing home, where the contaminated dust caused lead poisoning in their children. Lead poisoning is still with us in children with pica in old lead-painted houses, and even from burning battery casings [9].

Methylmercury: "Strange incidents occurred in villages along Minamata Bay in [the] Kyushu district in Japan, in which many cats went mad and died. These incidents were the prelude to [an] epidemic of a mysterious disease in human beings" [10]. Thus began a description of the neurologic disorder that swept the area in the 1950s. The disease was caused by fish contaminated with methylmercury derived from factory waste dumped into the Bay. The effect on the human conceptus was not noticed at first, but eventually 40 children with cerebral palsy were identified in a population where only 1 or 2 cases were expected during the interval before fishing in the Bay was forbidden [11].

The value of analyzing preserved specimens was dramatically demonstrated by Dr. M. Harada and his associates at Kumamoto University [12]. They knew that in Japan the dried umbilical stump is kept by the family for decades in a plain rice-paper wrapper. Study of the umbilical stumps from a sibship of 6 children born over the years spanning the epidemic in the 1950s showed a peak in methylmercury content in parallel with the factory's mounting productivity. Unexpectedly, analysis of the dried umbilical stumps from another family with children born 20 years earlier also showed a peak in methylmercury content which paralleled a smaller peak in factory production during the late 1930s. Then it was recalled that an unexplained small outbreak of a neurologic disorder had occurred at that time. Subsequently, methylmercury has polluted water, fish, and people in

Niigata, Japan, and outbreaks of neurologic disorders have occurred in various parts of the world where grain coated with the chemical as a fungicide and meant for planting, was mistakenly used for baking. The worst epidemic was in Iraq in 1971, where more than 6,000 people were affected [13].

Asbestos: Beginning in 1956, a clinician in South Africa observed a cluster of patients with a rare tumor, mesothelioma. A survey revealed 33 cases, 25 of which were traced not to work exposures, but to living near open-pit asbestos mines as children [14]. Subsequently, the marked excess of bronchogenic carcinoma found among asbestos workers was linked to an interaction with cigarette smoking [15]. This finding raises a question about such an interaction in U.S. children exposed to fraying asbestos-sprayed schoolroom ceilings [16], and who later take up smoking.

PCBs: Polychlorinated biphenyls, contaminated with dibenzofurans, used as a heat-transfer agent in Kyushu, Japan, leaked into cooking oil during its manufacture. About 1,200 people who ate food prepared in the oil developed chloracne. Nine infants, in utero when exposed, were small for dates at birth, had transiently darkened skin, and 2 were born with teeth [17]. An effect from PCB-contaminated breast milk has been described by the same Dr. Harada [18] who studied the dried umbilical cords in relation to Minamata disease. PCBs have since been found to pollute chicken feed, rivers, and fish in the U.S. and elsewhere [19].

PBBs: Polybrominated biphenyls, mistakenly added to cattle feed in Michigan, caused debilitation and death. The cause was unknown until a farmer whose herd was devastated and who persisted in believing the feed was responsible, finally had his suspicion confirmed, in part by accident. A gas-chromatograph was mistakenly left on too long, and showed a late-occurring peak that proved to be due to PBBs [20]. PBBs, PCBs, and dioxin (TCDD) are deposited in fat and best excreted in the fat of breast milk. A study in Michigan revealed that about 96% of women in the lower peninsula of the state had PBBs in their breast milk [21]. This chemical, which killed cattle, has not been shown conclusively to cause illness in the most heavily exposed people.

Dioxin: In 1976, a runaway reaction at a factory that made trichlorophenol in Seveso, Italy, burst from its enclosure and drifted downwind as a toxic cloud. Wildlife and domestic rabbits died. About 40 children developed chloracne in about 2 weeks [22]. As yet, a massive study has shown no other well-substantiated effects from the areawide contamination.

In Moscow Mills, Missouri, a waste oil dealer agreed to dispose of chemical byproducts from a bankrupt factory where hexachlorophene had been made. He simply mixed the chemical with the waste oil in his tank trucks, and then sprayed it on the dirt floor of horse arenas. Sixty-three horses died, along with 11 cats, 4 dogs and hundreds of birds [23]. The cause was traced ingeniously to

2,3,7,8-tetrachlorobenzo-p-dioxin (TCDD). The children of the horse arena owner played on the contaminated floor, but suffered only transient symptoms — and one child developed a hemorrhagic cystitis which cleared in a few months [24].

The Love Canal: The story of the Love Canal is too well known to be retold here, except to note that 82 chemicals intermixing in a waste dump have as yet caused no illness in children substantially exposed at home, school and play. The potential problem of areawide contamination by mixtures of chemicals in dumps, only recently recognized, is formidable.

The atomic bomb: The most extensive and longest running study to date of a massive environmental exposure involves the atomic bomb survivors of Hiroshima and Nagasaki. Clinical, epidemiologic and laboratory surveillances have revealed teratogenesis, carcinogenesis, cytogenetic abnormalities, and cataracts. Increased mortality from causes other than cancer has not been found. Seven measures of heritable genetic damage have revealed that the effects are not frequent enough to be detected in the population studied. Psychologic effects probably are experienced by all of the survivors, but objective evidence is less than we would like to have.

It is important to note that after the qualitative adverse effects were defined, emphasis shifted to dosimetry and the consequences of low-level exposures [25].

ANIMAL STUDIES

Wild and domestic animals may be affected along with human beings (PCBs, dioxin, methylmercury) or without detectable human disease (PBBs). Studies of experimental animals usually come after human or veterinary observations suggest a "new" environmental pollutant. A notable exception: hexachlorophene was found to cause brain damage in experimental animals. The use of the chemical in a protective rinse against skin infections of newborn infants was controversial until 1972 when 600 kg of baby powder in France was accidentally mixed with 36 kg of hexachlorophene and killed 36 babies (data unpublished due to legal restrictions while the case was in litigation).

CLINICAL OBSERVATIONS

Almost all known human teratogens and carcinogens have been first recognized by alert patients or their physicians. The hypotheses thus generated are then tested epidemiologically and in the experimental laboratory.

Clusters have thus led to recognition of environmental causes of human disease. Some "rare" illnesses, however, are frequent enough to cluster by chance. Leukemia is an example. Despite valiant efforts over 20 years, study of time-space leukemia clusters has not identified any new leukemogens [26].

SOME STEPS IN THE EPIDEMIOLOGIC STUDY OF AREAWIDE CONTAMINATION

Take a census: In 1968, the military sought to learn through a series of workshops what sorts of action should be taken, should a nuclear disaster occur. A psychiatrist who specialized in disaster studies suggested that an effective way to diminish the population's "loss of orientation" is to take a census [27]. A census not only enumerates people (including children), but also gives them a sense of belonging to society again. In registering the population it is important to obtain a unique identifying number, such as a Social Security number, if possible, to aid in follow-up studies.

Obtain personal history of exposure: As part of the census one should obtain some measure of exposure dose: how far the person was from the source, for how long, etc. For an instantaneous exposure, e.g., the atomic bomb, the information needed is readily recalled and concerns only a moment in time. At the Love Canal the duration of exposure must vary with the places of residence, work, play, and school, as well as with sources of food and drink.

Identify the exposure: Uncertainty about the nature of an exposure increases public alarm. As soon as possible the agent and its impurities should be identified. In Seveso analysis of the dioxin-contaminated soil was handicapped by lack of appropriate laboratory procedures. Exposures from the atomic bomb were unknown until they could be estimated as part of a nuclear weapons test in Nevada. In this test samples of Japanese housing were constructed for estimating radiation exposure within [28]. At the Love Canal the great mixture of chemicals has leaked unequally in various directions through underground streams that change course over time.

Clearly, identifying pollutants and establishing doses can be difficult. It is important to obtain specimens of soil, vegetation and animals — domestic and wild, for evaluating exposures of people. In Seveso, caged domestic rabbits, in whose livers dioxin was especially concentrated, were a valuable guide to human exposures [29].

Preserve human specimens: Human tissues may provide some indication of exposures or body burden many years after exposure — and in fact long after death; e.g., lead in the bones of ancient Peruvians [30]. Study of mummified umbilical cords for methylmercury content at Minamata Bay deserves mention here as well as above. Teeth, hair and dried blood spots are among inadvertently preserved specimens that have been informative about environmental exposures long since past. One should seek to preserve not only specimens that can be measured for chemical content, but also tissues in which subclinical effects may serve as a biologic dosimeter; e.g., cytogenetic abnormalities as revealed in preserved lymphocytes. Also, the urine or feces might be studied in short-term assays for mutagens/carcinogens.

MEASURING EFFECTS

Review the literature: To speed searches of the literature a "crisis response team" has been established at Oak Ridge National Laboratory that can provide a printout within 24 hours concerning the effects of a chemical. The information provided is from human observations and laboratory studies, reports of which are often too widely scattered in the literature or too recent to be readily available from published indexes in local libraries. The information available may help determine the components of the study to be made.

Use existing data sources: Surveillance of some health effects can be made by using data from vital certificates, hospital charts, insurance records or special disease registries. In the United States, the birth certificate gives the birthweight, may provide some information about congenital malformations, and contains the mother's maiden name, of use in follow-up studies. The death certificate diagnoses, unavoidably imperfect, are nonetheless a good indication of causes of death. Outpatient and inpatient surveillance of hospitals can provide information about acute effects. In the area of Mt. St. Helens, for example, a surveillance of hospitals revealed no serious acute diseases from the volcanic ash [31]. For long-term follow-up, the National Death Index [32] should soon simplify determination of deaths in cohorts of people under study. The Index, located at the National Center for Health Statistics, allows identifying information for exposed persons and control groups to be matched against a list of persons who have died in the United States year by year. When matches are found, the state is identified in which the death occurred, and a copy of the death certificate is requested in the usual way. The simplest surveillance may well be through record linkage, rather than by questionnaires, interviews or medical examinations.

Which agency has jurisdiction? When a potentially toxic exposure has occurred, one can scarcely stop to puzzle out which government agency is responsible for dealing with it [33]. The simplest solution is for state health authorities to call the Center for Environmental Health of CDC in Atlanta; Dr. Glyn G. Caldwell for radiation exposures, Dr. Henry Falk for chemical exposures, or the Officer on Duty at night or on weekends. Their recent activities have included responses to medical problems related to explosions at Mt. St. Helens volcano and of the Titan II missile. Insofar as possible, local and state health departments should deal with small-scale contaminations without calling for federal assistance. It is extremely important, however, that such aid be sought promptly when it is really needed. Thus, the federal agency can share the responsibility with the local health authorities. In a comparable situation, the Regione Lombardia in Italy established an international committee of "garanti" to advise on medical activities after the dioxin contamination in Seveso.

THE SPECIAL SUSCEPTIBILITY OF THE FETUS AND CHILD

In 1973, a conference was held at Browns Lake, Wisconsin, on the special susceptibility of the fetus and child to chemical pollutants [34]. The proceedings, characteristically, were not widely read. Proceedings seldom are. Since the conference was held, we have learned of PBBs in Michigan; dioxin in Seveso, Moscow Mills and elsewhere; DBCP; kepone; the Love Canal and many other chemical dumps; heavy metal absorption in children living near smelters; the fetal alcohol syndrome; and asbestos dust from schoolroom ceilings. The effects include sterility, infertility, embryotoxicity, birth defects, possibly transplacental carcinogenesis, low birthweight, skin lesions, nerve impairment, immunologic disorders, cancer, and fear of late effects. To the usual modes for transmitting pollutants, we have added lactation, important in regard to fat-soluble chemicals, and dust worn home on the parent's work clothes.

Problems with pollutants have multiplied in the 7 years since the Browns Lake Conference. The reproductive process continues to be particularly sensitive to adverse effects. We need to use recent experience, so rapidly accumulated, to set priorities and formulate plans for evaluating current and future difficulties with environmental contamination.

Dr. LEWTAS. There have been several reviews of these human monitoring methods especially as a result of the Love Canal problem and the inadequate chromosome study EPA was involved with. There have been several reports, both from the Office of Health Research in EPA and together with Health and Human Services which survey those techniques, those which we recommend, and how they could be applied in a scientifically adequate way. Of course it helps to have the largest population possible for such studies. Like Dr. Anderson suggested, it is important to have proper cohorts so you can decide whether or not the effect you see is really related to exposure to chemical wastes.

It is difficult, though, from such a study to say that one particular individual's chromosome abnormality is due to their particular exposure. That is the difficulty scientifically. But you can gather enough evidence that you can say there is a certain likelihood and this could make the basis for a decision.

Mr. ROWLAND. Are you familiar with the AMA position on dioxin espoused 3 or 4 weeks ago?

Dr. CARNOW. Are you talking about on the first day, or the fourth day?

Mr. ROWLAND. I am talking about their final position.

Dr. CARNOW. I think the final position was refutation of what appeared to be an irresponsible statement. I think that certainly it was not a studied remark. And unfortunately, I was in Paris at the time. I was quoted in the newspaper in relation to the toxicity of dioxin, not a direct comment on it. Again I think it was just something that was done in the heat of a convention resolution, and certainly those individuals in the AMA who were responsible refuted it as soon as they recognized the nature of the statement. It certainly was not a responsible scientific statement.

Mr. ROWLAND. Dr. Karrh, do you have a comment on that?

Dr. KARRH. I don't have much to add to what Dr. Carnow said, except the original statement itself, I don't think, addressed totally the toxicity of dioxin, except to imply at least that the problem posed by dioxin had been magnified by the press reports. This was passed by the AMA house and on the fourth day was rescinded by action of the same body. I think it was left, though, that the AMA position regarding dioxin is back where it was to start with. That is that they don't have a position on dioxin as such.

They still have a position on agent orange. The AMA Council on Scientific Affairs passed that in January. Agent orange became notorious because of the dioxin contamination.

Mr. ROWLAND. Medical specialists are confused, too, maybe.

Dr. KARRH. I think we are, Dr. Rowland.

Mr. LEVITAS. Dr. Anderson?

Dr. ANDERSON. Could I add something about the risk assessment approach? I think the reason for a lot of the confusion here is the reference to what we have done for years at EPA. It is exceedingly difficult to establish these effects in humans. And although it certainly is exceedingly important to continue trying, we feel that we have enough information, enough tools available on some compounds such as dioxin, to do a risk assessment with respect to different disease endpoints.

In this case we did evaluate the data and decided dioxin certainly has the potential of causing cancer, from animal studies, also reproductive effects. We established what we thought were plausible dose response curves for these diseases and we also did an exposure assessment that took into account soil levels and potential for human exposure. This information formulated the basis for concern in the areas such as Times Beach. And so I guess I wanted to just mention that we don't feel we have to wait for a smoking gun.

I think there might be eternal confusion about direct observation in humans. I realize it is the cutting edge of your bill. It is my own feeling that if you are going to do victim compensation, it is probably going to have to be based on some probability of occurrence rather than certainty because it is so exceedingly difficult to establish these kinds of things in humans.

So I just didn't want to leave you with the feeling EPA was sitting and waiting.

Mr. ROWLAND. Let me say I think what you did was correct, because you functioned under the authority that you were given, which says when there are releases to the environment of any pollutant or contaminant which may present an imminent and substantial danger to the public health. And I think you, EPA, acted entirely correctly from that standpoint.

Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you.

Before I recognize Mr. Sundquist I would just like to find out, Dr. Karrh, would you agree or disagree with what Dr. Anderson just suggested, that in establishing the standard for victim compensation, because of the difficulty in establishing what the standard would be if there were one, reasonable likelihood? Is that what you said?

Dr. ANDERSON. Some set of guidelines that would address potential possibilities or probabilities.

Dr. KARRH. I would agree as long as this were done on a case-by-case determination by a scientist or group of scientists and not have presumptions built into the Act where you automatically presume a certain trigger and once you pass that trigger, you compensate, because people in general develop diseases that tend to cluster. If you have an automatic presumption, automatic trigger, and just because of clustering you trigger that, then you have instigated something that perhaps should not have been in the first place.

But if you use some type of scientific judgment in each case, science panel or scientific board, so that you look at it on a waste site or geographic area at a time, then I would agree with what Dr. Anderson said.

Mr. LEVITAS. Mr. Sundquist.

Mr. SUNDQUIST. Thank you, Mr. Chairman.

Dr. Karrh, my impression from your testimony is that the wagons are in a circle and you are taking your last stand. I would say there is enough blame to go around in all areas. I think the Federal EPA standards today for dumps are not much better than the standards that allowed us to have a Love Canal. I think the chemical industry is continuing to admire the emperor's clothes when in fact he is naked. And there are some things we have to face up to. I think the industry position perhaps has created the situation where we are today where there is a lot of confusion.

My question is: On the first page of your statement you mention that you believe that individuals harmed by exposure to hazardous substances should be compensated by those that caused injuries. That makes sense to me. Then on page 2, though, you say that a special work group was put together to determine if there was a relationship between waste sites and widespread harm. You served as chairman of the group and found that claims of such relationship run counter to the experience of CMA member companies, stating "Moreover, independent surveys have failed to detect significant health problems."

On page 4 you talk about Hardeman County, TN. As I understand what you are saying, the blood tests for some of the residents who used water from a contaminated aquifer displayed a temporary abnormal liver function which disappeared in most cases after the source was removed. Do you have a copy of that study with you?

Could you furnish me with a copy of that study?

Dr. KARRH. I would be more than glad to furnish you a copy. I do have a copy with me but it has been punched and in a notebook. I will submit it to the record and send you a copy personally.

Let me first say, though, that I am sorry you get the impression from our testimony that we have our wagons in a circle and that we are taking our last stand, because we certainly are not.

Mr. SUNDQUIST. Let me tell you why I think that.

Dr. KARRH. Let me finish, if I may, sir.

Mr. SUNDQUIST. You may not want to finish if I tell you why. Let me tell you why. Because as I read through this, from page 1, you think there may be some injuries and responsible people ought to pay. Then on page 2, a study group was created which found that there really isn't much of a linkage. Then as I read on page 4, the case of Hardeman County, TN, the impression I get is that there is not really a problem in Hardeman County, Tennessee. That is the reason I concluded the wagons are in a circle.

I am not trying to blame anybody in particular. I think we ought to take a whole new approach to hazardous chemicals and encourage the private sector to recycle. But when I get to the middle of page 4 and read about Hardeman County, my impression is that you don't think there is a problem in Hardeman County, TN.

Dr. KARRH. If I may continue with the answer I started earlier.

Mr. SUNDQUIST. Absolutely. We want to give you a chance to give all your answers.

Dr. KARRH. It is because we feel there is a public perception of problems and there may be in certain areas where there has been a problem like Hardeman County, TN, where a small number of people did suffer some reversible effects as a result of waste, chemical waste contamination of their water acquifer. But what we are saying is that we think that before Congress passes some type of legislation to address an issue that may not exist, we ought to first determine does the issue exist; second, what is the magnitude of it; and, third, what is the best way to approach it from a legislative standpoint. Don't legislate and then go looking for a problem for which you have a solution, but look for the problem first, then fashion the solution that addresses that problem.

In Hardeman County, this was a rural area with a very small number of people who got their water from an acquifer that was contaminated. Drinking the water did not give them a problem. It was finally determined that they probably had the problem as a result of showering in the water that became heated and the volatiles that were in the water came off, and they inhaled them and developed some abnormal liver function test. As soon as they changed their source of water supply, their symptoms went away, liver function tests went back to normal and the problem from a health standpoint was corrected. That has not corrected the acquifer problem.

We feel before we jump in and do something precipitous we may later regret we ought to find out exactly what we should do.

Mr. SUNDQUIST. Now, the reason I made the statement that I made, now that you have had a chance to comment on it, is that Hardeman County is in my district, so I have some knowledge of Hardeman County. In a lawsuit currently pending before the U.S. district court, Judge Odell Horton has encouraged the attorneys, several times in the course of the trial, to work out a settlement. It is a $2.5 billion lawsuit. The judge has indicated that he is going to make a large judgment against Velsicol if they don't settle.

Dr. Alan Levin of San Francisco testified that Hardeman County residents are kind of sitting on a time bomb. Dr. Jack Sawyer, a clinical psychologist, found mass trauma after contamination of well water in the Toone-Teague area, saying, "You see these kinds of psychological effects in a refugee camp."

Steve Sterling, a Toone-Teague resident, said, "I don't know what's going to happen. Everybody's sick out there, kids and all."

From the Memphis Health Department, Everett C. Handorf, a sanitation engineer, said that chemicals buried there could contaminate Memphis water in 30 years—if not cleaned up.

Several doctors, liver and intestinal disease experts, testified that Toone-Teague residents may have a 10-percent greater likelihood of getting cancer.

One hundred two residents have been examined. A doctor from Vanderbilt, Dr. Robert K. Rhamy, testified that the specific illnesses of several plaintiffs probably were caused by chemically contaminated water. It is not just an isolated incident. It is not just a few people. It has not been a temporary abnormal liver function which is going away. It is a $2.5 billion lawsuit with permanent injury, with a lot of things involved, and I think in your testimony you are underestimating the extent of the problem.

In fact, from reading your testimony, I would have the impression—I don't know whether my distinguished colleagues would have—but I would have the impression that the study group that you headed found no relationship between waste sites and widespread harm.

Then I look at Hardeman County, and as stated here, that the blood tests for some of the residents displayed a temporary abnormal liver function which disappeared in most cases with removal of the source of exposure. From what I can determine the problem is much more serious than that. In the next few weeks we are going to find out how serious it is. I would also submit that the Federal Government has to share in a lot of the blame for where we are.

But I say that in statements like that which you have read and furnished us, you are viewing the emperor with clothes on.

Dr. KARRH. I, ~~think,~~ Mr. Sundquist, what we are saying here is that we have reviewed the literature, the data that are available to us. The Hardeman County study was written up in the scientific literature and was peer reviewed in the scientific literature. The data you have presented obviously came out of a lawsuit which we have not had access to. We probably could have, but we have not. But that is another indication that the current, existing system works. Because these people do have access to the courts and to the tort system.

There is not an indication from what you have just said that this tort system has broken down in this particular case such that there needs to be some other type of compensation mechanism. If we are faced with a situation after we have done other appropriate studies that indicates the tort system can't handle the load that is going to be presented to it or that there are indeed victims such as you have described here that have not been written up in the scientific literature yet, then the chemical industry will totally support that.

Our position is that if the system now works, let us look to see if we need a better system, because people do have access to the existing system.

Mr. SUNDQUIST. Doctor, my point is, with all due respect, that in the statement you just made you are talking about the issue we are discussing today. But in most of your testimony I think you are underestimating the problem to imply that we don't have the serious problems that do exist. When you say you will move your family to Times Beach, I would submit to you, you can buy a lot of property there very cheaply. It might be a good investment if you can find a lot of other people who will move there with you. I think what gets the industry in trouble is not recognizing that we do have a serious problem. There are people out there who do have claims, and let us talk about that, as opposed to trying to leave the impression, right or wrong, that there is not a problem in Hardeman County, TN, or there is not a problem in Times Beach, MO.

I think there is a problem. Now, let us talk about whether or not we need Federal legislation. That is what we ought to be talking about, as opposed to trying to induce the impression that we don't have serious problems with hazardous chemicals.

Dr. KARRH. I think, Mr. Sundquist, that is what we were addressing, is the fact we have reviewed the data that are available and have concluded that we cannot, in the scientific data, find there is a serious problem. There is a lot of talk about it. The public has a perception that there is a problem. We think we ought to do the studies to determine if there is a problem. We totally support the studies. But not just pick up the emotional side of it, assume there is a problem and then do something based on that assumption rather than adequately taking care of whether or not there is a problem and what is its magnitude.

Mr. SUNDQUIST. That concludes my questions. I will take another turn, Mr. Chairman.

Mr. LEVITAS. Thank you. We will be going around again.

Are you familiar, Dr. Karrh, with the proposed legislation that would require the chemical industry manufacturers to provide proof of efficacy of pesticides before they could be marketed and provide that information to the public or purchasers of the pesticide? Would you think that would be useful information for a purchaser to know that if he is buying a product, a pesticide or some other fungicide or herbicide, that it is effective?

Dr. KARRH. That is a pretty hypothetical question that you are asking. I would assume the companies and people who were purchasing it would not want it purchased unless it was effective. Our position, though, is that if there is a toxic characteristic of a material, whether we are selling it into commerce to other companies or whether we are selling it to the public, that we should provide adequate information as to what the toxic characteristics and hazards of that material is, if that is your question.

Mr. LEVITAS. I will take that as the basis for what I am going to ask.

Mr. ROWLAND. Mr. Chairman, you asked for the efficacy, didn't you?

Mr. LEVITAS. Yes. But he introduced toxicity.

Dr. KARRH. I think I answered the efficacy by saying that if we sold a product we would want it to work, or we wouldn't sell it.

Mr. LEVITAS. Let me take the toxicity because that might even be a better illustration of what I am trying to find out. I am sure Du Pont, for example, developed some sort of scientific or medical protocol before it markets a product to ascertain its toxicity.

Dr. KARRH. Yes, sir.

Mr. LEVITAS. What type of cause and effect determinations are made in terms that would exist between a given chemical product and health effect or health risk? What degree of certainty do you seek to achieve?

Dr. KARRH. As I mentioned earlier, we have a toxicology laboratory started in 1935. On any product we plan to introduce or any chemical substance we plan to use to which our employees may be exposed, if data do not already exist indicating what are the toxic characteristics of that product, then we will develop a battery of toxicity tests that will be done in this laboratory.This will include a lot of different tests.

The tests will depend largely upon what use is going to be made of the product, what the exposures are likely to be and how it is going to be handled. Then each of these tests are evaluated by scientists on an individual test basis. Based upon the results of the tests and results of their evaluation the scientists decide several different things on the chemical.

First is it too toxic to try to handle? If that is the case, we stop there and don't do anything else. Or does it have certain toxic characteristics that require special types of controls and medical surveillance? If it is the latter, then we decide what those are. When we introduce it into our plant sites we put in those controls to protect our employees. Then if we decide to introduce a product into commerce and sell it to other companies or sell it to the public, we will take the same data and decide first is it safe for other companies to purchase from us or for the public to use once they have purchased it from us, and if we decide yes, then we decide what precautions we should give to the people who will be handling or using the material.

Mr. LEVITAS. Would Du Pont market a chemical product, bulk chemical or drug or pesticide, without conducting tests so that it knows with 100-percent certainty that there are no adverse health affects that will result from exposure?

Dr. KARRH. Mr. Levitas, I don't think there is any material made that there is 100 percent certainty that no adverse effects will result from exposure. Table salt, water and other things are quite toxic if not handled properly. So the answer to your question is we market many chemicals that have toxic characteristics, some of which are quite toxic. But we know, based upon the data we have developed and our evaluation of the data that if the protocols we develop are followed, people will not suffer adverse health effects from exposure to these materials.

Mr. LEVITAS. Let me get back to my efficacy question. Would Du Pont market a product that it does not have 100-percent certainty would be efficacious?

Dr. KARRH. Since I am not sure how you are using that word, would you define it for me, please.

Mr. LEVITAS. Well, that it works.

Dr. KARRH. That is a marketing definition, not scientific, and I am not prepared to answer that question.

Mr. LEVITAS. You don't know the answer to that question.

Dr. KARRH. That is correct, I do not know.

Mr. LEVITAS. What degree of evidence does a company like Du Pont seek to achieve or attain either as to efficacy, or as to toxicity before it make a decision on marketing. I mean do not run every conceivable scientific test that might be available to evaluate what the health effects of the chemical would be, or what the efficacy achievement might be?

Dr. KARRH. I am going to have to excuse myself on answering the efficacy question because I really am not qualified to answer that. That is a marketing question and I am not in the marketing area. I can address the toxicity question. The answer to the question is no, we don't run every conceivable toxic test that you could run because then you couldn't afford to buy our products if we did. We run the tests that we feel, based upon our scientific evaluation of the compound and other compounds like it and our scientific evaluation of the early toxicity tests that we do, need to be done.

We will run every test we feel helps us determine or better define what the toxic characteristics are. But once we have decided that we have adequate toxicity information, that we know that chemical can be handled safely, then we probably will not run additional tests from then on.

But we do run adequate tests so that we can tell our customers and our employees what steps need to be taken to make sure people don't suffer harm from exposure to that material.

Mr. LEVITAS. So you run enough tests that satisfy yourself, that satisfies your company, that a product is safe enough to be used under whatever cautions are given even though it hasn't run all the tests capable of being run on that product?

Dr. KARRH. That is correct. We make a scientific determination on each chemical as to what are the toxic characterisics and what protective measures need to be taken.

Mr. LEVITAS. Let me tell you where that leads me. Congress has to make decisions. EPA has to make decisions and courts have to make decisions. And I believe on something short of absolute certainty as to cause and effect linkage.

Mr. Molinari is going to be asking some questions, I know, about the tort aspect of it. But from my point of view, in cases such as chemicals that are in hazardous waste sites, whereas all of you have testified, there may be long latency periods before we have actual manifestation of the particular abnormality that is caused or may be caused by that, maybe 10, 15 years down the line, I don't think that it is appropriate to ask Congress or EPA to wait and expose the population to those potential effects until we have had that 15 or 20 years of experience when the consequences of failing to take some action in the meantime will potentially expose large segments of the population to high risk. And that there has to be a place in time where, based upon scientific literature, reports of health consequences, individual health diagnoses, where there are statistically large numbers of occurrences that are different from what you would normally expect, that at that point, Congress ought to take some action, and so should EPA, without waiting for the long-term study that establishes beyond the shadow of a doubt the linkage, causal linkage that you seem to be suggesting should be done.

Dr. KARRH. Mr. Levitas, I think you probably think we are proposing to wait 10 or 15 years on each and every dump site. In fact, the chemicals that are in disposal sites now have been in use in industry for many, many years, some of them 30, 40, 50 years. The work force that has been exposed to those chemicals, at usually higher concentrations than what they would be exposed to at disposal sites, have been studied extensively.

The chemicals have been studied from a toxicological standpoint. The work forces have been studied. So we don't have to wait the 10 or 15 years. We know that once we determine what is in a waste disposal site and we go back to the animal data that we have and to the work place data that we have, we already have satisfied the 10- or 15- or 20-year, latency period in most cases.

Taking dioxin as an example, the first industrial accident in which large numbers of people were exposed was in 1949 in Nitro, WV. That population has been studied extensively since then. That is a period of 34 years. They are still being studied by the University of Cincinnati. So we don't have to wait for a dioxin disposal site like Times Beach for another 10 or 15 years. We have good data. That is precisely what my CMA work group did, was look at the occupational data we had on the chemical substances that were in disposal sites and decide whether or not there were likely to be health problems from these and, if so, what was the magnitude of them. We concluded that there was not likely to be any great number of health effects from these. And there was time to do the more in depth studies that need to be done, like the study we are going to be doing and like the studies the ATSDR will be doing.

Mr. LEVITAS. Let us take the dioxin situation where you say there has been a long period of time to study the health effects. There is a large body of evidence as to the properties of dioxin and we are constantly receiving reports of waste sites containing dioxin or dioxin-composed chemicals. We have a situation in Michigan which is current. There are several reports of sites in New Jersey, Times Beach, and I could go down the line, where dioxin is involved.

If I understand what you have said, based on your reading of the literature, that you don't see evidence of adverse health consequences from people living in proximity to these sites containing the dioxin.

Dr. KARRH. That is correct with the dioxin. Consequently, we feel further study needs to be done. Because we haven't seen these health effects, we are not putting people at risk during the relatively short period of time we are suggesting be taken to develop the magnitude—

Mr. LEVITAS. Consequently, the policy conclusion that would be drawn from that is therefore Congress shouldn't act until there is more proof—or proof, and EPA shouldn't act based on the present state of the data base.

Dr. KARRH. No, sir. We feel that EPA should get on with cleaning up the orphan land disposal sites now as Superfund required that they do. That was part of the lawsuit that was filed. We feel that the disposal sites should be cleaned up.

EPA should act in this area. We feel that CDC and EPA should act on the health studies.

Mr. LEVITAS. Why do you think that should be done? See, that is what I don't understand. I am going to get to Dr. Carnow in a minute. We are talking about in the case of Superfund, spending $1.6 billion for openers, and it is going to be a lot more than that in my judgment if the program goes forward, and I am satisfied it will.

But why should we spend that type of money if there is not evidence that there are health consequences resulting from the existence of these hazardous waste sites? Why should we do it?

Dr. KARRH. There are several reasons we should do it. First, the public perceives there is a problem and it should be taken care of for that reason.

Mr. LEVITAS. That is a lot of money to spend for cosmetics.

Dr. KARRH. Well, I think the chemical companies put it into the Superfund for that purpose. It is a type fund that once it is spent, EPA can come back for recovery of the funds they spent out of it from the people who created the hazard in the first place. So it would still be coming out of the chemical industry. The fund was created for that purpose.

Mr. LEVITAS. I don't want to get into that aspect of it because I would argue that any time there is a charge, a cost, it is going to be passed on to the public ultimately in some shape or form. So I am not really interested—I am just saying there is a lot of money that is being spent to do something.

Now, the only reason that you have given that it is being spent is because the public perceives that it is a problem. But your studies and working group has concluded there really isn't evidence of a health problem.

Dr. KARRH. The only reason that was the only reason I gave was because you cut me off before I could finish. These disposal sites that are out there, many have failed. They are leaky sites. They should be cleaned up and cleaned up expeditiously.

Mr. LEVITAS. Why?

Dr. KARRH. Thank you, sir. They should be cleaned up expeditiously because since they are leaking they will leak into areas where people can be exposed to them. So we should get on with the cleanup of those sites. We should make sure that our future efforts are such that we don't create sites like that. But we have to do some type of work, some type of study to determine which sites to clean up first.

We have 419 priority sites. EPA has added another hundred, or so, to that. EPA does not have the resources to clean that up. So we have to do something in setting priorities to clean them up under Superfund. But we think the sites should be cleaned up and certainly hope EPA will do something toward cleaning them up.

Mr. LEVITAS. Have you finished?

Dr. KARRH. Yes.

Mr. LEVITAS. You haven't answered my question. If those chemicals in those sites do not pose a health risk to people, or to use your words, there is no evidence of significant health problems from waste sites, if that is the case, I, for one, would strongly object to spending that kind of money to clean up these sites just for cosmetic reasons. If these sites were filled with benign materials, distilled water, and it was seeping out, I think it would be a dreadful mistake in terms of public policy and use of public resources to spend $1.6 billion cleaning up those sites.

Why do you think these sites should be cleaned up if they don't pose a significant health hazard?

Dr. KARRH. I think I have already covered that, but what we have said is, based upon the data we have now, we don't see a significant health hazard. There is a public perception of a problem. Some of the sites are leaking and are likely to create a problem in the future. So let us clean those sites up. Let us continue, before we pass some type of victims compensation legislation, to look at the scientific data and determine if there is a need to compensate victims.

We know we need to clean the sites up because the sites, some of them, are leaking, some of them have gotten into acquifers. Hardeman County, TN, is a good example. And those sites should certainly be cleaned up. But that doesn't mean that because the sites need to be cleaned up that we have to have victims before we clean them up. That is waiting, as some have said, to count the bodies. We don't think we ought to do that at all. We think that where a site may pose a hazard it ought to be cleaned up.

Mr. LEVITAS. Why would it pose a hazard?

Dr. KARRH. Because it may be leaking, it may be getting into acquifers.

Mr. LEVITAS. And the chemicals that are leaking could cause an adverse health effect in the future.

Dr. KARRH. They may in the future cause adverse health effects. The studies we have done indicates they are not significant adverse health effects at this time, but we don't know what will happen 10 or 15 years from now.

Mr. LEVITAS. We will take the public perception and put that over here so we don't need to address that anymore. Let us come back to the "may cause health effects in the future." And you would agree that the potential of causing health effects in the future is a justification for cleaning up these sites under Superfund?

Dr. KARRH. Yes, sir, I would agree with that.

Mr. LEVITAS. Thank you.

Dr. KARRH. But that doesn't mean we have health effects now.

Mr. LEVITAS. Dr. Carnow, would you care to comment on that briefly?

Dr. CARNOW. Briefly?

Mr. LEVITAS. Yes, I said briefly.

Dr. CARNOW. All right. You have to understand we are good friends, but we have some disagreements.

Mr. LEVITAS. I sensed that. I wanted to find out what the nature of those disagreements were.

Dr. CARNOW. First of all, I think that there are at least 400 priority sites and there have not been anywhere close to 400 studies. It is really presumptuous to say there is no health effect. I think, for example, if you did a study of dioxin in a remote area in Canada you probably would not find health effects. If you do them in Times Beach, I submit you will find those.

The fact is that we have difficulty with some studies. There is an enormous amount of data on health effects of dioxin. We have to take that because that seems to be this contention point. EPA says in its document it is the most deadly of all manmade chemicals. I think they say it is possibly, or probably the most—I think we all recognize that it kills in incredibly small amounts.

The study or studies to which Dr. Karrh referred, first of all, were studies which were funded by Monsanto. We have examined people from Nitro. I can assure you that our results are different than the results of those studies. And when we can we will publish them. They are in litigation now. We can't publish them. The studies were done by a dermatologist who was mostly interested in chloracne. And the fact is that the studies at BASF in 1953 and the reports in the literature which again I know have 23 volumes of reprints on the health effects of dioxin, and that does not constitute an exhaustive group of reprints.

There is no question it is extraordinarily toxic. I think to deny that is to deny reality. I think again in terms of the problems we face, I don't know the extent of the problem. I don't have the confidence Dr. Karrh has that there is no problem, or that we find no problem. I feel that out there is an extraordinary potential problem. Dr. Karrh agrees.

If this stuff leaks out, it is dangerous. I submit that some of that has been there for 50 years and it has leaked out, and we don't know how dangerous it is. I am not suggesting that all of us are going to die imminently. I am suggesting it requires intensive effort. But while we make those intensive efforts, if we find levels of dioxin in the community, then we have to take every measure to protect that community.

I understand the staggering costs. I understand all those things. But I certainly would not put my family into that community. I have examined children from those communities and they are very sick children. They are children who have brain damage. They are children who have seizures. They are—I just examined a 6-year-old child that has a blood cholesterol that would stagger you. You don't see that in 6-year-old girls.

Again I just—I don't want to be accused of emotionalism. I think people become emotional because they feel threatened. I don't think people feel threatened because they are emotional. I think there is a basis for all of this emotion. I think people are concerned about their families and so on.

I think our response should not be an emotional response. A scientific response. But I think it has to be a serious response that looks not only at what is in the dumps, but looks at what has happened to communities around them. They are going to be very expensive studies.

But on the other hand, if we know that there is a dump, and if we know that there is leaking, and if we find any levels at all in soil or water that may be a problem, we have to either at least examine people promptly as you point out, you can't wait, or else we move people away until we can make a determination of their health conditions or the problem that exists.

I can only tell you in looking at—they are very insidious problems. Looking downwind from two smelters in two different States we found little children who are retarded. That represents a serious cost to society. An enormous cost. We estimate $260,000 to raise that child who has mental retardation. Very subtle. We have to look with great care. I don't think we can say we may not have a problem at all, and we are going to clean it up, because people have emotional problems in this country.

Mr. **Levitas**. Let me give Dr. Karrh his due on that. I think he finally said that we ought to clean it up, not just for public perception reasons but also because there is the potential of adverse health effects.

Dr. **Karrh**. That is right. After I got a chance to start back again.

Dr. **Carnow**. And I said we don't know whether there are potential or determined health effects.

Mr. **Levitas**. We have made some progress. Let me say this one thing and then conclude. I know Dr. Karrh wants to make some response on what Dr. Carnow has said. If we could or should take action based on potential health effects in the future, and therefore clean up hazardous waste sites which are leaching out hazardous materials into surface waters and groundwaters and the soil, then should we not also consider providing a system for compensating the human beings who are being affected or exposed to those materials at the present time rather than waiting a long number of years to bring about this scientific certainty that you would—in other words, shouldn't we provide as much concern and response on the likelihood of this problem occurring to individuals as we do for cleaning up the property where the materials are stored?

Dr. KARRH. If we have determined that people have been exposed to these materials and are suffering health effects as a result of that and a scientific determination is that there is in fact the reason for it, then sure they should be compensated. But we feel that if we clean up the sites as Superfund is supposed to, we wouldn't run as great a risk of having people who have to be compensated.

We don't feel we need to put in some type of mechanism now to compensate people if we don't know people out there need to be compensated. But we do need to get on with cleaning up the sites and determine if there are people who need to be compensated. That was part of my testimony. Although we have not seen evidence of significant health problems and while that evidence leads us to believe there is not likely to be a significant health problem, we fully agree the evidence in this area requires a thorough scientific review.

Dr. Carnow's comment regarding the Nitro, WV, study, the study group was headed by a dermatologist who has a special interest in chloracne, but he is also head of the Kettering Institute which has a multidisciplinary approach and probably is the best recognized occupational and environmental health laboratory. He did not do the study by himself. He had a team of several different disciplines.

Mr. LEVITAS. Dr. Rowland asked me to yield. I will now do so, then recognize Mr. Molinari.

Mr. ROWLAND. Thank you for yielding, Mr. Chairman. You mentioned, Dr. Carnow, children who had brain damage, I believe. Maybe I missed the point somewhere. Were these people who were exposed to dioxin?

Dr. CARNOW. No, the children I am talking about were children—you may have come in after I discussed this—were children who lived downwind from lead smelters.

Mr. ROWLAND. Thank you, Mr. Chairman.

Mr. LEVITAS. Was one of those sites the Dallas situation that we have investigated?

Dr. CARNOW. No. The first one was found theoretically. I was asked by the city of El Paso to look at the question of sulfur oxides. When I looked at the emission data I found that 800 tons of lead had come out of that smelter, and suggested to the health commissioner that they might have a lead problem. He suggested they had never had a case of lead poisoning in El Paso or that area.

We then examined some of those children for him. And we found that large numbers of them did, in fact, have chronic blood poisoning. But it wasn't the kind of blood poisoning you see in Chicago where a child eats some leaded paint and develops an encephalopathy. It was very chronic, very quiet, very subtle. The children were weak, anemic, retarded, dropped out of school. That kind of problem.

This has been found since that time in El Paso. That has been found in other areas around the country in relation to some of these things. This doesn't mean, of course, that every industrial plant is spewing out poison. I am not implying that.

Mr. LEVITAS. I understand. Mr. Molinari?

Mr. MOLINARI. Dr. Karrh, I would like to pick up again at the point where the gentleman asked you about the question of cleanup. I would like to see if I correctly understand you and your recommendations, that we do need to clean up the sites. What sites were you referring to?

Dr. KARRH. I think any site, Mr. Molinari, that presents a hazard or may present a hazard should be cleaned up as soon as we possibly can. Then any other site that is on the priority site list should be cleaned up. But we have to have some order of priority because our resources are finite.

Mr. MOLINARI. Let us see if we can narrow this a bit. Would you agree that there is a need to clean up the 419 priority sites that were established by EPA?.

Dr. KARRH. Based upon what I know about those sites, from having read only EPA's very short summary, I would say yes there is a need to clean them up but they should be cleaned up in some order of priority so we make sure we take the worst first.

Mr. MOLINARI. I think we all agree to that. What if there is not enough money in the Superfund to achieve that purpose? Would you agree that more funds should be collected according to the present formula in order to have an adequate sum to complete the job?

Dr. KARRH. I think we first ought to start using the money we have in there for the purpose for which it was intended and begin to clean up the sites and then determine whether or not there will be enough money. That $1.6 billion fund was to clean up the orphaned sites. The Government could first use the money to clean up the sites, and then at the same time, the legal side of the Government could try to recoup that money back from the people who put the material there.

So if it works the way it should, the fund would replenish itself based upon what was being brought in from the legal action that was taken. If later it is determined that this is not adequate to clean up the sites, then there ought to be a need for further funding. But we ought to start cleaning up the sites——

Mr. MOLINARI. Aren't they in fact doing that now?

Dr. KARRH. I am not aware that large numbers of sites have been started. I know EPA has started some sites but I can't tell you which ones.

Mr. MOLINARI. Are you allowing for the number of sites where it is apparent from experience that EPA is not going to be able to collect reimbursement because the companies involved are bankrupt or otherwise out of business?

Dr. KARRH. That is what the Superfund was set up for; the orphaned sites where a responsible party could not be determined. In most of the cases where there is a responsible party, EPA does have redress back to that responsible party.

Mr. MOLINARI. It would appear obvious from your answers that there is not going to be enough money to clean up the 419 sites. You identify them as orphaned sites, although you do recognize the fact that there are some responsible parties from whom we can collect a contribution. The reason I ask this is that we have had testimony that indeed there wouldn't be enough money to clean up 100 sites.

Dr. KARRH. I think until we start cleaning them up and until EPA starts going back to the parties that they can identify as responsible and taking the appropriate action to recoup what they have spent cleaning up that site, we really wouldn't know whether there will be enough money or not. We should proceed with the clean up and see if there is enough.

Mr. **MOLINARI**. I am asking a simple question. Assume hypothetically there is not going to be enough. That in fact the testimony we have is accurate. That we only have enough to clean up 100 sites. Do you recommend we go further and collect more moneys and proceed to clean up the remaining sites?

Dr. **KARRH**. I didn't come prepared to make a legislative recommendation to you at this time. What I would like to do is just submit something back to the record on behalf of the chemical industry.

Mr. **MOLINARI**. Fine. I would be glad to accept that.

Dr. **KARRH**. Thank you.

[The information received from Dr. Karrh follows:]

E. I. DU PONT DE NEMOURS & CO.,
Wilmington, DE, August 22, 1983.

U.S. HOUSE OF REPRESENTATIVES,
Subcommittee on Investigations and Oversight, Committee on Public Works and Transportation, Rayburn Building, Washington, DC.

Mr. Molinari had asked that CMA comment on whether Congress should go further and collect more monies for Superfund (see transcript p. 111 and 112). In response to this question we wish to state that it is not possible at this time to determine whether or not the $1.6 billion to be raised through Superfund taxes will ultimately prove to be adequate. It is clear, however, that there is now plenty of fund money available and that EPA and Congress have time to assess the fund adequacy issue carefully before acting to impose additional taxes. As of May 31, 1983, the U.S. Treasury Department, Bureau of Government Financial Operations, Division of Financial Management, Trust and Revolving Funds Branch, reported a net balance in the fund of over $470 million. Thus, the fund contains substantial monies.

The amount of money in the fund is not, however, the sole factor to consider in determining its adequacy. The level of federal funding needed will depend on several key factors. Perhaps the most important are the number of sites needing cleanup, the cost per site, and the degree to which private funding will be used for cleanup (either "up front" or to reimburse fund expenditures).

It is too early in the administration of the Superfund cleanup program to make accurate projections on any of these key factors, but experience thus far clearly shows that private funding is being used a great deal. Many sites are being cleaned up totally from private funds, and many others are being cleaned up with substantial percentages coming from private funding. According to EPA, over $118 million had been collected by the end of 1982 through private party contibutions to Superfund waste site cleanup.

One example is the Fridley site in Minnesota (which is the No. 1 priority site on EPA's proposed list of 419 sites). There the FMC Corporation recently agreed to perform a surface cleanup and groundwater monitoring program for approximately $6 million. In addition, last month the Minnesota Mining and Manufacturing Company committed to clean up certain of its sites in Minnesota for $6 million.

There are also recent examples of groups of companies agreeing to contribute shares towards the cost of cleanup. At the Bluff Road site in South Carolina, 14 companies contributed $1.8 million. At the Chem-Dyne site in Ohio, 112 companies contributed $2.4 million. At the Deerfield site in Ohio, 8 companies contributed $2 million. At the Wade site in Pennsylvania, 32 companies contributed $1.7 million. Thus, it is clear that private funds are a significant source of cleanup funds in addition to Superfund.

In addition, we should note that EPA is now preparing a comprehensive report, in compliance with Section 301(a)(1) of CERCLA, assessing these key factors in order to "project any future funding needs". CERCLA Section 301(a)(1)(C). This report is due in December 1984. In light of the facts that there is now a balance in the fund of almost ½ billion dollars and that EPA is currently carefully assessing future funding needs, we believe that it would be inappropriate for Congress to impose new taxes now.

I am also enclosing the following for inclusion in the record:

1. The study of residents in Hardeman County, Tennessee, as requested at page 83, line 1896, entitled "An Environmental Health Survey of Drinking Water Contamination by Leachate from a Pesticide Waste Dump in Hardeman County, Tennessee", from the January/February 1982 *Archives of Environmental Health*, Vol. 37, No. 1.

2. A copy of the UAREP study, as requested on page 113 of the transcript, entitled "Report on the Feasibility of Organizing a Study to Assess the Potential Health Hazards of Waste Disposal Sites Within the United States", by Universities Associated for Research and Education in Pathology, Inc., dated June 22, 1983.

3. A report entitled "Epidemiologic Study of Workers Exposed to Acrylonitrile", by Maureen T. O'Berg, Ph.D., from *Journal of Occupational Medicine*, Vol. 22, No. 4, dated April 1980.

4. A report entitled "Angiosarcoma of Liver in the Manufacture of Polyvinyl Chloride", by J. L. Creech, Jr., M.D., and M. N. Johnson, M.D., from *Journal of Occupational Medicine*, Vol. 16, No. 3, March 1974.

5. A study entitled "Mortality Study of Workers in the Manufacture of Vinyl Chloride and its Polymers", by Irving R. Tabershaw, M.D., and William R. Gaffey, Ph. D., from *Journal of Occupational Medicine*, Vol. 16, No. 8, dated August 1984.

6. A report entitled "Respiratory Cancer in Relation to Occupational Exposures Among Retired Asbestos Workers", by Philip Enterline, *et al.*, Dept. of Biostatistics, Graduate School of Public Health, University of Pittsburgh, from *British Journal of Industrial Medicine*, Vol. 30, 1973.

7. A report entitled "Lung Cancer After Employment in Shipyards During World War II", by William J. Blot, et al., from *The New England Journal of Medicine*, Vol. 299, No. 12, dated September 21, 1978.

8. A report entitled "Dust Exposure and Mortality in Crysotile Mining, 1910-75", by J. C. McDonald, *et al.*, from *British Journal of Industrial Medicine*, Vol. 37, 1980.

9. Report entitled "The Pathogenesis of Asbestos-Associated Diseases", by J. D. Craighead and B. T. Mossman, from *The New England Journal of Medicine*, Vol 306, No. 24, dated June 17, 1982.

The above reports (3 through 9) of workers incidence of disease resulting from exposure to acrylonitrile, vinyl chloride, and asbestos are for inclusion at page 125 of the transcript.

I also enclose for the record preliminary reports relating to studies of the Brookfield landfill by The Bureau of Preventable Diseases of the New York City Department of Health. This work was discussed at page 155 of the transcript. Also enclosed for the record is a critique of these reports.

Sincerely,

BRUCE W. KARRH, M.D.,
General Director,
Medical, Safety and Fire Protection.

Mr. MOLINARI. You make reference in your prepared text on page 7 that you were going to submit a copy of the NAREP feasibility study for the record, but apparently you don't have a copy of the study with you.

Dr. KARRH. I have a copy of the study with me. I do not have enough copies to submit the number required. I can submit it for the record either by giving it to you now, or I can submit it to the record later, whichever you would prefer.

Mr. MOLINARI. I would like to have as many copies as you have available. We would like one submitted for the record.

Mr. LEVITAS. Without objection it will be made part of the record.

Dr. KARRH. I only have one copy with me I can submit to the record at this time. Actually the one I have with me is a draft. I will have to submit a copy.

Mr. LEVITAS. Do you have one now we can reproduce?

Dr. KARRH. No; the one I have is a draft. I thought I had one of the originals with me, but I don't.

Mr. MOLINARI. The study was released on July 7. I take it it is in final form?

Dr. KARRH. That is correct.

Mr. MOLINARI. If you would, turn to page 4 of your statement.

Dr. KARRH. I have a final copy of the study, but this is my personal copy that has my scribbling.

Mr. MOLINARI. We wouldn't want that.

Dr. KARRH. There is nothing I have in here that I would mind you seeing, but I think I would prefer to keep this one and submit one for the record.

Mr. MOLINARI. Fine; if you would turn to page 4, toward the bottom of the page you talk about occupational exposure and health data providing an indication of the health effects that might be expected if similar exposure patterns were encountered by the public. Then you go on to say:

> Since we saw no significant increased incidence of chronic disease among employees in the chemical industry, we concluded that widespread increased incidence of chronic disease among the public is also unlikely.

Now, before I heard you testify that there should be a differentiation made between the various chemicals. Here you are prepared to make the statement that regardless of the chemical that has been produced by the industry you represent, you have seen no significant increase in incidence of chronic disease. Is that a fair statement?

Dr. KARRH. I am not sure I understand what you are asking.

Mr. MOLINARI. When we asked the question before about the exposure to toxic chemicals, I think you made a point, a very definite point, that we have got to think in terms of what chemicals we are talking about. There are some that will not cause a problem. There are others that are more serious and have to be looked at more carefully, and we should be careful to distinguish what we are talking about.

But here you are making a general statement that there was no increased incidence of chronic disease among employees in the chemical industry. Now, I take it that that means all chemicals prepared or manufactured by the chemical industry.

Dr. KARRH. It means potentially all chemicals. What we were doing here was trying to look at the data that were available. We determined that there was not much data available that was specific to waste disposal sites and to people who may have been exposed to that.

In order to try to get some understanding of what may be the magnitude of the health problem from waste disposal sites if there was one, we went to the next data that we had that indicated, people would be exposed to chemicals and for which we had some health data. That is employees of the chemical industry.

We evaluated those data. Based upon the results of the studies that have been done in that industry and the fact that chemical industry employees would be expected to be exposed to larger concentrations of the material, than would people living out in the community that may be close to a disposal site——

Mr. MOLINARI. How do you come to that conclusion?

Dr. KARRH. I haven't reached a conclusion yet.

Mr. MOLINARI. OK.

Dr. **Karrh**. We were able to make inferences that the likelihood of people in the industry suffering adverse health effects from chemical exposure would be greater than people in the areas of the waste disposal site because of the differences in the potential exposure. That tells us that, although we cannot conclude that people in the waste disposal sites would not have health effects, at least it tells us that there should not be a pressing, imminent problem that means that we have to take action now without doing the proper studies that need to be done to determine if there is a problem.

Mr. **Molinari**. In the case of those working in the chemical industry, don't they wear protective gear that is supposed to insulate them from adverse health effects?

Dr. **Karrh**. They would wear protective gear if they were exposed to materials at concentrations that had been shown or were likely to cause adverse health effects, but generally that is at a much higher level than what one would expect to find out in the community where there are a lot of different factors than at work, such as an open air system where the concentrations of the material would be dissipated.

You have to determine first is there any exposure occurring out in the community. In many cases the material would not be released in concentrations in which there could be exposure as large as chemical industry people would be exposed to.

Mr. **Molinari**. Are you telling us that there are cases in the industry where people are working and are exposed to chemicals that could cause a health problem and that the industry is not in those cases providing protective clothing?

Dr. **Karrh**. I am telling you that there are cases where people in the chemical industry are exposed to chemical substances. Based upon the scientific data that we have, though, we have been able to determine at what level the chemical substance is likely to cause a problem. We then put in a factor to make sure the employees aren't exposed at that level. You can't operate a chemical plant at zero exposure to a material.

The only way you can is by what is called remote operation. There are very few processes that people are willing to run through remote operation because of the difficulty of running, so you do have some exposure.

Mr. **Molinari**. It is fair to say the rate of exposure, then, would differ from chemical plant to chemical plant, and from chemical to chemical as well?

Dr. **Karrh**. That is correct, between companies, between plants and between chemicals.

Mr. **Molinari**. OK. So taking your statement that you can't operate at zero exposure, are there workers then that would be seriously exposed in the industry?

Dr. **Karrh**. The companies, an individual company, based upon the data they have, will determine what would be the safe level for an employee to be exposed to a material for the period of time that that employee would be working. They will put in a safety factor below, but the employees may be exposed at some level of exposure. This is taken into account by the Occupational Safety and Health Act where they give you a level above which you can't expose people.

Mr. MOLINARI. Isn't that supposed to be a safe level?

Dr. KARRH. Yes; based upon the information that is available and we draw our scientific conclusions from it.

Mr. MOLINARI. Dr. Carnow, I saw you shaking your head rather vigorously. I certainly welcome your comment on what has just been said.

Dr. CARNOW. I didn't notice my head shaking. However, the TLV, which is the threshold limiting value, which is one which has been assigned as a level workers can theoretically work at 8 hours a day, 40 hours a week for a working lifetime, every one of those that has been reviewed in the last 10 years has been changed.

I think when we think about TLV's, we have to think of them as convenient levels for industrial hygienists so when they do measures for air quality they have some kind of guidepost. I don't think anybody suggests these levels are appropriate for all workers.

In addition, like toxic waste dumps, many workers are exposed to multiple materials which may impact on a single target organ. So while TLV's are useful, like toxic waste dumps, I think there is no assurance that those levels are safe.

Let me just suggest that the arsenic level has been reduced two or three times; asbestos level, four or five times; vinylchloride level remarkably, and so on and so on. So I think that there has to be that—of course, I guess that is why I shook my head.

Mr. MOLINARI. There are, I think, 168 hours in a week. If we have a person who lives near a toxic dump who works out in the garden or is otherwise exposed for 168 hours a week, and were we to attempt to draw a comparison to somebody who works in the chemical industry who has the latest state of the art protective gear, could we draw a comparison between the two and make any assumptions that are reasonable assumptions?

Dr. CARNOW. You can make comparisons between animals and humans and various humans, but you have to be very careful about how you extrapolate your data. For example, at the level of 5 parts per million of sulfoxide, it was considered safe in the workplace. Studies we did suggested that at .14 parts per million, individuals with chronic bronchitis became ill. At .3 parts per million, less than one, some individuals who are marginal died. So it depends on the population.

We also carried out a series of studies with the National Academy of Sciences on the relationship between air pollution and cancer, particularly lung cancer. It suggests that there is a great variability of risk in individuals. And an individual who was exposed from the time he or she is born until old age to something may present a very different problem from that of a worker who in fact is part of a survival population.

Workers are the healthiest individuals in our society. Many of them, if they are working in a place where the nose or throat or chest—that can't handle the TLV, they find another job. Again, you have to be very careful about extrapolation of those kind of data.

Also, the caveats you introduced about protective devices, children eating snow and playing snow angel are different from somebody who is wearing a respirator and body suit.

Mr. **Molinari**. Doctor, wouldn't it be a fair statement in some cases that continuous low level exposure by unprotected individuals could be more harmful than the exposure experienced by somebody working in the chemical industry who, during the limited period of time that he is working with the protective gear, is exposed to higher concentrations; that the person in the first category could have a greater health risk? I say, depending upon the chemicals.

Dr. **Carnow**. There are a lot of variables. An individual working in a plant where three or four people get sick, people zero in on it. You do air quality measurements and make corrective measures. In a community, you have individuals going to various doctors. They may be going to a doctor with a rash. One doctor says it is cosmetics; another says it is tight pants, which is what was said with one group of people who were exposed to dioxin.

Again, I think that the problem we have in the community is that most of these are subtle. Acute problems are easy. If you have a spill and people are sick and dying, everybody moves in on it. It is this very insidious low-grade, seeping into a water supply, getting into the air and dust—those are the kinds of things I think we have to be concerned about here—extraordinarily difficult problems, but those are the ones we must be concerned about.

Yes; there are very significant differences. Low-level chronic exposure may very well be a serious problem. The body can compensate for a certain amount of some toxic agents. We can get rid of 300 micrograms of lead a day from our body, but when we exceed that we begin to accumulate it. So low-level, long-term exposure may be a significant problem.

Mr. **Molinari**. I am pleased to hear you say that. Not pleased, but it corroborates my reading on the subject. I question the statement, "Since we saw no increased evidence of disease among employees in the industry, we concluded that widespread incidence of chronic disease among the public is also, unlikely." I think the comparison there is not a fair comparison, and the conclusion is not a fair conclusion.

Dr. **Carnow**. Well, in a sense it is, because we can extrapolate, and we do extrapolate from effects, because the occupational setting is a microcosm of the community. I think we just have to be very careful about how we extrapolate the data.

Dr. **Karrh**. May I comment on that, Mr. Molinari?

Mr. **Molinari**. You sure may.

Dr. **Karrh**. The point I have made on that—and I have spoken it several times here today—is that we were using that to draw inferences for ourselves as to whether or not there is a pressing problem that requires immediate action. Or do we have time to address the problem properly by evaluating its extent, magnitude and what is the best solution.

All we wanted to do was see if we had something that today we had to take some type of action, or if we had 6 months or 12 months or a little bit of time to more thoroughly evaluate the problem. That is the only reason we resorted to those data.

We agree with Dr. Carnow that these data don't give us direct information, but they certainly give us some very valuable inferences that we can use in deciding our future course of action.

Mr. **Molinari**. Do you have any studies available that we could look at which show high incidence or abnormal incidence of disease where workers have been exposed to toxic chemicals on the job?

Dr. **Karrh**. Yes; we do. I will be glad to submit some for the record for you.

Mr. **Molinari**. Is there a title for that work?

Dr. **Karrh**. Acrylonitrile Epidemiological Study reported by myself to the Federal Government in May 1977, and was subsequently published in a journal that shows an increased incidence of cancer among workers exposed to acrylonitrile. That was at a time when the Government standard was much higher than what industry was operating on itself.

[The study referred to follows:]

Epidemiologic Study of Workers Exposed to Acrylonitrile

Maureen T. O'Berg, Ph.D.

This retrospective cohort study of 1,345 male employees with potential for exposure to acrylonitrile analyzes cancer incidence and mortality from 1956 to 1976. Expected numbers based on company and national rates have been computed based on person-years. The analyses consider calendar time, payroll classification, occupation, duration of exposure, severity of exposure, and latency. Overall, 25 cases of cancer occurred, with 20.5 expected based on company rates. Of these, eight were respiratory cancer cases, with 4.4 expected. Excesses were found primarily during the 1970-76 time period among wage roll employees who had worked during plant start-up. A trend toward increased risks was seen with increased duration and severity of exposure. Twenty cancer deaths were found, with 17.4 expected according to company rates. Since many cancer cases were recently diagnosed and are living, it may be premature to evaluate mortality statistics. These findings, coupled with results from tests in laboratory animals, raise the serious suspicion that acrylonitrile may be a human carcinogen.

Acrylonitrile is a chemical frequently used in the production of plastics, synthetic rubber, and fibers. It has been estimated that in the United States 125,000 workers are potentially exposed to acrylonitrile.[1] The chemical is structurally similar to the human carcinogen vinyl chloride, and, in fact, is known synonymously as vinyl cyanide. In 1977, Maltoni et al[2] reported that rats exposed to acrylonitrile by inhalation and gavage showed "borderline oncogenic effects." Preliminary results of rat studies conducted at Dow Chemical Company for the Manufacturing Chemists' Association[3] revealed excesses of papillomas of the stomach, Zymbal gland carcinomas, tumors of the central nervous system, and masses of the mammary region.

Although previous studies in man have identified acute effects of acrylonitrile,[6,7] none has specifically addressed the question of its carcinogenicity. This study was undertaken to determine whether workers potentially exposed to acrylonitrile at a DuPont textile fibers plant in Camden, S.C., exhibited increased risks of developing cancer.

Acrylonitrile has been used at the Camden plant since 1950. Work history cards showing demographic information and dates of assignment to areas where there was potential for exposure to acrylonitrile have been maintained at the plant and are available for both present and former employees in production and in maintenance.

Cohort Selection and Exposure Classification

Through an examination of more than 10,000 work history cards, 1,345 men who had had potential exposure to acrylonitrile at some time between start-up in 1950 and the cutoff date of December 31, 1966, were identified. These men were followed up until December 31, 1976. December 31, 1966, was chosen as the cutoff date for cohort eligibility so that a minimum of 10 years of follow-up would be possible for all members of the cohort. No women were included in the cohort, as none had held assignments in potential exposure areas during the years 1950 to 1966.

Plant environmental monitoring data unfortunately are not available for the 1950-1966 period. In the absence of quantitative exposure data, a qualitative assessment of severity of exposure in jobs was made by the author and a committee of six employees with long-term service in the acrylonitrile area. This committee included representatives from production, maintenance, engineering, and personnel. Manufacturing process changes and personal protection were documented chronologically in establishing the exposure levels. Three categories were used to indicate relative level of exposure: high, moderate, low. Each level is a composite measure of the intensity and the frequency of exposure, reflecting the guidelines established by the committee.

After the exposure potential of jobs had been assessed,

From the Epidemiology Section, Medical Division, E. I. DuPont de Nemours and Company, Inc., N-11400, Wilmington, DE 19898.

Completed in partial fulfillment of the Ph.D. degree in Epidemiology at the University of Pennsylvania.

Reprinted from Journal of Occupational Medicine
April, 1980, Volume 22, No. 4
pp. 245-252
JOM 1980

three methods were used to determine whether a specific individual had ever held any of the jobs which involved potential exposure to acrylonitrile.

1. *Record Examination* — Work history cards were thoroughly examined. This was sufficient for determining exposure potential in most cases for wage roll employees and in many cases for salaried employees.

2. *Recall* — Because information contained in work history cards for wage roll personnel who worked in general services maintenance and for salary roll personnel does not always include specific assignments, it was necessary in some instances to rely on memory in determining whether or not an individual had held a job in which there was potential for exposure. Those individuals involved in recalling the jobs of persons in the cohort were members of supervision who had long service and were familiar with both the jobs and the people under consideration.

3. *Survey* — Work history cards for salary roll employees are not as detailed as those for wage roll employees. All active salary roll employees whose work history cards indicated they had worked in an area where they could have had exposure to acrylonitrile were asked to fill out a form indicating which of their assignments, if any, did constitute exposure to acrylonitrile.

Follow-up Procedures

After coding procedures had been established, pertinent data were recorded at the plant. The coded sheets were sent to the epidemiology section of the medical division where a computer tape was created. Medical data for individuals in the cohort were added to the tape. Sources of medical data include: (1) The DuPont Mortality File. This file was begun in 1957 and contains information on deaths which have occurred among all active employees and among pensioners. (2) The DuPont Cancer Registry. The Registry was begun in 1956 and includes diagnoses of cancer among active employees enrolled in the company's accident and health insurance program and a record of deaths which have occurred among active employees. Approximately 95% of company employees are enrolled in this health insurance program. Claims must involve disability of at least eight consecutive days, must indicate the diagnosis, and must be signed by the attending physician. (3) Death Certificates. Death certificates were obtained for former DuPont employees who were identified as deceased by the Social Security Administration (SSA) and were a source of additional cause-of-death information. A more detailed description of these data sources can be found in a previous publication.[8]

Of the 475 former employees whose names were sent to SSA, the vital status of 102 could not be determined. The name and date of birth of each of these persons were sent to the Motor Vehicle Division of the Department of Highways and Public Transportation in Columbia, S.C. This division provided information indicating the most recent date of driver's license renewal, when available. Former employees for whom the Motor Vehicle Division had such information were considered alive until the date of license renewal.

Additionally, a list of the names of former employees of unknown status was given to the plant committee members with instructions that vital status, when known, be recorded on the list.

Following these procedures, it was concluded that, of the 475 former employees, 41 were deceased, 402 were alive, and the status of 32 was unknown as of December 1976. In summary, vital status was determined for 98% of the cohort.

Coding of diagnoses and causes of death was done by trained nosologists in the medical division, according to the International Classification of Diseases. Death certificates were obtained from various state health departments for all 89 members of the cohort whose deaths were known to have occurred between 1957 and 1976. Furthermore, pathology slides were available for 16 of the 25 diagnosed cancer cases. These were sent to the Armed Forces Institute of Pathology, whose examination of tissue specimens confirmed in all instances the original diagnosis in the DuPont files.

Analytic Methods

The cancer incidence and the mortality experience of the cohort were analyzed. The numbers of person-years of observation were calculated as described below. For analyses of incidence (cancer diagnosed among persons actively employed at DuPont) the numbers of person-years were calculated from the date of first exposure after January 1, 1956, when the Cancer Registry was begun, until the earliest of the following events: date of cancer diagnosis, date of death, date of termination (resignation, discharge, or retirement), or December 31, 1976. Periods of unemployment (e.g., lay-off or military leave) were not included in the total number of person-years. Time periods were rounded to the nearest tenth of a year.

For mortality analyses, the numbers of person-years were calculated from the date of first employment after January 1, 1957, when the DuPont Mortality File was begun, until the date of death, or the date lost to follow-up, or until December 31, 1976, whichever occurred first. Table 1 presents, by calendar year and payroll status, the compilations of person-years of observation used in the morbidity and mortality analyses.

Expected numbers were computed using the packaged USDR program developed by Monson[9] in which age-specific rates are multiplied by the appropriate numbers of person-years to give expected numbers. The expected numbers are then summed over all age strata, resulting in an overall age-adjusted expected number. This number is compared statistically to the observed number, using

probability tables for the Poisson distribution (one-tailed).

Cancer incidence rates obtained from the DuPont Company and from the 1969-1971 survey conducted by the National Cancer Institute (NCI) were used in the calculations. Several sets of mortality rates were used: DuPont Company rates, rates for U.S. white males, rates for South Carolina white males, and rates for white males in the five counties contiguous to the plant.

For comparison purposes, DuPont rates are preferable to those derived from the general population because the general population includes persons hospitalized or otherwise too sick to be employed and thereby yields "expected numbers" which are higher than those determined using a healthier employed population as the referent. The magnitude of an excess risk, then, is underestimated when expected numbers are based on general population rates because of the so-called "healthy worker effect." Furthermore, ascertainment of cases is generally consistent within DuPont, whereas methods employed elsewhere might differ.

Incidence Data

Through a search of the DuPont Cancer Registry from 1956 to 1976, 25 cases of cancer were identified among employees from the acrylonitrile cohort. Superficial skin cancers are not included in this count, since these tumors are not uniformly reported and seldom involve either a week's disability or death. The 25 cases of cancer include eight lung, three colon, three prostate, two bladder, and one each of thyroid, nasopharynx, penis, esophagus, brain, leukemia, lymphosarcoma, Hodgkin's disease, and malignant melanoma.

Two additional cases of lung cancer in individuals who should have been included in the cohort but were inadvertently omitted due to clerical error were discovered from examination of work history files for all employees with cancer at the Camden plant. Both of the employees had short duration of exposure: two months in one instance, three months in the other. Both are now deceased. These cases/deaths are excluded from the tables which follow, since proper adjustment of expected numbers is impossible. An estimate of the "miss-rate" among noncases was made by sampling one out of every 14 plant records. Among this sample of 465 employees, there were five similar omissions, giving a 1% error rate.

The numbers of cases observed were compared first with the numbers expected based on DuPont Company rates. The time span of 1956-1976 was divided into three periods. For each time period company rates for wage roll employees were applied to the number of person-years accrued among wage roll employees in the cohort. Similarly, rates for salary roll employees were applied to the number of person-years accrued among the salary roll group. Rates were computed after exluding the experience of the cohort.

The cohort was dichotomized so that results for men with exposures of less than six months and for those with exposures of at least six months were considered separately. Results for cancer, all sites combined, are presented in Table 2 and for cancer of the respiratory system, in Table 3. Numbers for other sites are too small for detailed comparisons. In the overall cohort, however, three cases of colon cancer were observed, compared with 2.2 expected, and three cases of prostate cancer were observed, with 0.9 expected, based on DuPont rates.

It can be seen in Table 2 that among the 217 persons with less than six months of exposure only one case of cancer was observed, compared to 1.5 expected. There will be no further discussion of cancer incidence among persons with less than six months of exposure. Among persons with at least six months of exposure 24 cases were observed, compared to 19.0 expected. Among these cases were eight respiratory system cancers, compared to 4.1 expected (Table 3).

The experience of men first assigned to the area in 1950-1952 during start-up operations was analyzed separately from that of men assigned after 1952. For the men whose exposure began in 1950-1952, results for cancer all sites combined, are presented in Table 4 and for cancer of the respiratory system, in Table 5. Table 4 shows that among persons with at least six months of exposure beginning after 1952, fewer cancers were observed than expected (1 compared to 5.9). Among those whose first exposures occurred during the period 1950-1952, 23 cases were observed, compared to 12.9 expected ($p < 0.01$). Twenty of these cases developed among wage roll men, with 11.2 expected, and three occurred among salary roll men, with 1.7 expected.

Generally, wage roll employees have greater potential for exposure than do salary roll employees since they are more apt to work continuously where the process is carried on. Among the wage roll employees in the 1950-1952 group, a slight deficit of two cases is seen in each of the first two time periods, whereas a significant excess of 11

cases is noticeable in the period 1970-1976. This pattern is largely due to the distribution of respiratory cancers among wage roll men, there were eight cases observed, compared to 2.6 expected ($p < 0.01$). Six of these cases were diagnosed during the period 1970-1976, 1.5 were expected (Table 5).

Wage roll employees include operators, maintenance mechanics, and laboratorians. Table 6 shows, by occupation, the observed and expected numbers of cancers of all sites combined for wage roll employees with at least six months of exposure.

It can be seen that the excess cancer among wage roll men during the period 1970-1976 occurred principally among maintenance mechanics (10 cases observed, compared to 3.7 expected) and to a lesser extent among operators (6 compared to 3.5). From 1970 to 1976, three respiratory system cancers were found among maintenance workers, compared to 1.8 expected, and three among operators, with 0.9 expected (Table 7). Among laboratorians cancer incidence was close to expected.

In an effort to explore the possibility of a dose-response relationship, duration and severity of exposure have been analyzed. In the analysis of duration, numbers of person-years have been distributed so that the contribution to a given calendar year is evaluated according to duration of exposure as of that year. Thus, for a man exposed from 1960 to 1970, the number of person-years of exposure has been tallied in the 0-4 years duration-of-exposure category for 1960-1964, in the 5-9 years category for 1965-1969, in the 10+ years category after 1969. An internally developed computer program was designed for this purpose.

Table 12. — Comparison of Expected Numbers of Cases, All Cancer, According to Referent Population, Acrylonitrile Cohort, Camden Plant, 1956-1976

	Observed	Expected Based on NCI Rates (1969-1971)	Expected Based on DuPont Rates
1956-1964	3	6.0	4.5
1965-1969	2	6.4	5.0
1970-1976	20	13.1	11.0
Total	25	25.5	20.5

The analyses of duration are presented in Tables 8 and 9. No trends are seen among salary roll employees. Among wage roll men with a least six months of exposure the risk for cancer of all sites appears to increase with increasing duration of exposure, as summarized below.

Duration	**Observed**	**Expected**	**Ratio**
<5 years	4	5.4	0.7
5-9 years	6	5.0	1.2
≥10 years	10	4.3	2.3

The trend in ratios is stronger in the 1970-1976 period, which approximates a 20-year latency period since first exposures in the early fifties.

Duration	**Observed**	**Expected**	**Ratio**
<5 years	3	2.9	1.0
5-9 years	5	2.3	2.2
≥10 years	9	2.8	3.2

The numbers of respiratory system cancers are quite small, therefore, ratios have not been calculated.

In considering severity of exposure, results for men with only "low level" rankings have been presented separately from those for the remainder of the cohort, which includes men with some "moderate" and "high" rankings. In Tables 10 and 11 it can be seen that, in the "low level" group, cancer incidence was close to expectation: seven cases observed, compared to 6.4 expected, for all sites, two observed, compared to 1.4 expected, for respiratory system. In the "all others" category, which represents higher exposure levels, 17 cases were observed, compared to 12.6 expected, for all sites, six were observed, compared to 2.7 expected, for respiratory cancer. Again the comparisons for the 1970-76 period are more striking: 14 observed, compared to 6.5 expected, for all

sites, five observed, compared to 1.6 expected, for respiratory.

The expected numbers presented thus far have been based on DuPont Company rates. In Table 12, the expected numbers based on NCI rates (Third National Survey, 1969-1971) are presented along with those based on DuPont rates. It can be seen that the expected numbers based on NCI rates are consistently higher than those based on DuPont rates. Further presentation of comparisons based on NCI rates has been omitted since the DuPont rates provide a more sensitive indicator of risks.

Mortality Data

Eighty-nine deaths were known to have occurred between 1957 and 1976 among persons in the acrylonitrile cohort. Death certificates were obtained in all instances. Table 13 presents the comparison of observed and expected numbers of deaths, based on DuPont Company rates for 1957-1976, in three time periods. Results show that among men with less than six months of exposure, 18 deaths occurred, compared to 11.2 expected. Among men with at least six months of exposure, 71 deaths occurred, compared to 66.2 expected.

Cause-specific mortality among men with at least six months of exposure is shown in Table 14. The numbers of deaths due to cancer and heart disease were slightly higher than expected. There was also excess mortality for accidents and suicides.

A more detailed presentation of mortality for cancer of all sites and for cancer of the respiratory system can be found in Tables 15 and 16 respectively. A total of 20 cancer deaths occurred in the entire cohort, compared to 17.4 expected, based on DuPont Company rates. The slight excess (18 observed, compared to 15.2 expected) was confined to wage roll men. As has been shown to be the case with incidence, any excess occurred during the period 1970-1976 (15 deaths observed, compared to 10.5 expected). Mortality from respiratory system cancers in the period 1957-1976 differed little from expectation: 8 deaths observed, compared to 7.1 expected.

Additional mortality comparisons have been made based on rates from the general white male population of the United States, the white male population of the state of South Carolina, and the white male population of the five counties contiguous to the Camden, S.C., plant. These comparisons are displayed in Table 17, along with the DuPont-based expected numbers. It can be seen that, as was the case with morbidity, the numbers of expected deaths based on the experience of the U.S. white male population are higher than those based on DuPont figures. Expected numbers of cancer deaths based on the state and county rates are slightly higher than those based on the U.S. rates, and again are higher than the DuPont expected numbers.

Discussion

The incidence data in this study show increased cancer risks for some subgroups within the acrylonitrile cohort. These data are limited to persons who develop cancer while still employed at DuPont. The mortality follow-up is more comprehensive in that it includes pensioners and former employees. However, most of the diagnoses have been recent — too recent in many instances to have resulted in death. Thus far, mortality findings in this study do not reveal an association between acrylonitrile and cancer, but it may be premature to evaluate mortality properly.

Causal relationships are difficult to establish in epidemiologic studies, since rigorous control of pertinent variables is impossible. Several criteria are used in determining whether an association is likely to be causal.[10] The strength of the association is considered. In this study the overall cancer standardized incidence ratio (SIR) for cancer based on DuPont Company rates for persons with at least six months of exposure is 126. The standardized mortality ratio (SMR) is 113. Within the entire cohort, the wage roll group works most directly with the acrylonitrile process. Furthermore, it was during start-up (1950-1952) that exposures were least contained. If the strength of the association is examined for wage roll employees who had at least six months of exposure and who began assignments during start-up, the SIR increases to 179 and the SMR to 143.

A dose-response relationship lends credence toward establishing causality. In this study, small numbers and a lack of quantitative exposure data hinder attempts to study dose-response. Nonetheless, a trend in the direction of increased risks can be gleaned from comparison of observed and expected incidence in three subgroups with increasing duration of exposure: less than 5 years, 5-9 years, and at least 10 years. The SIR increases from 0.7 to 1.2 to 2.3, respectively. Incidence analyses using the qualitative severity assessments show that persons with only "low" level exposures have close to expected cancer experience (SIR = 109), whereas those with higher exposures have higher risks (SIR = 135).

Temporal correctness of the association is an important consideration. In this study, the data are consistent with the hypothesis that a carcinogen appeared in 1950 and that excess cancer appeared 20 years later. Of the 24 cases which developed among men with area assignments of at least six months, 17 occurred at least 20 years after initial exposure. Of the eight cases of respiratory system cancer, six developed 20 years after first exposure. For the period 1970-1976, the SIR for cancer, all sites, for wage roll men who had had at least six months of exposure and who had worked during start-up is 304 and the SMR is 177.

The latency issue is important in the study of carcinogenicity. Most cancers develop long after initial contact with causative agents. Latency periods of 20 to 30 years are quite common with many known human carcinogens, e.g., asbestos, betanaphthylamine, chromium, and vinyl chloride.[11] The temporal relationship between initial exposure and increased risks in this study is consistent with existing knowledge.

Another criterion used to determine whether an association is causal is the consistency of the association across many studies. No other epidemiologic studies addressing the carcinogenicity of acrylonitrile have been published, and hence results of this study cannot yet be supported or refuted by other research. Animal studies have demonstrated carcinogenic response by several routes of administration. These offer some support and insight. A variety of tumors was found in rats, as was the case in this cohort. There is no correspondence of primary sites between the rat studies and this study. Specificity of response and organ consistency between animal species and man would provide a stronger case for causality. The multiplicity of primary sites may not be without biologic plausibility though. Acrylonitrile is carried throughout the bloodstream in humans, and thus could reach many target organs and systems.

Other factors which must be considered require discussion. Cigarette smoking is one. Smoking histories were unavailable at the Camden plant, but an effort was made to obtain information on the smoking habits of all persons in the cohort who developed cancer. Contact was made with employee associates and members of supervision to determine the cigarette smoking history of these individuals. It was possible to obtain this information for all except one of the employees who developed lung cancer. All for whom this information was available were smokers; however, this does not rule out an etiologic role for acrylonitrile, either alone or in synergy with cigarette smoking.

Other exposures must also be considered. The cohort was explicitly selected because of assignment to areas where acrylonitrile was present. This exposure did not occur in isolation, however. Exposure to dimethyl formamide, methyl acrylate, and other chemicals could also have occurred in many instances, but these substances are not suspected carcinogens. Previous or subsequent employment could also have involved other exposures. Personal factors such as diet, use of medication, and ethnicity have not been ascertained. These factors are known to affect the development of cancer. The problem of confounding factors is not unique to this study, nor to occupational studies in general, but it must be kept in mind when interpreting results.

Summary and Conclusions

Among 1,345 male employees who had potential for exposure to acrylonitrile at the Camden plant, 25 cases of cancer occurred, compared with 20.5 expected, based on DuPont Company rates. The excess was primarily due to respiratory cancer, with eight observed cases versus 4.4 expected.

These cancer cases were diagnosed primarily during the period 1970-1976, when highly significant excesses of all cancers and of respiratory cancers were seen. The excesses were found among wage roll employees who worked during the 1950-1952 plant start-up. A trend toward increased risks of cancer of all sites was seen with increased duration of exposure and with higher severity of exposure.

Eighty-nine deaths occurred among men in the cohort. A very slight excess of cancer deaths was found (20 deaths vs 17.4 expected). Since many cases were diagnosed recently in persons who are still alive, it may be premature to interpret mortality statistics.

These findings, coupled with results from tests in laboratory animals, raise the serious suspicion that acrylonitrile may be a human carcinogen. Further studies are needed to confirm or refute what appears to be an increased risk in certain subgroups of this cohort.

ABSTRACT. Ground water that was used as a source of potable water by residents of a small community became contaminated by leachate from a 300,000 barrel pesticide waste dump. An environmental health survey of the residents and an apparent control group was conducted to determine if any adverse health effects resulting from exposure to the toxic compounds, many of which were hepatotoxins, could be detected. The survey utilized a health questionnaire, a clinical examination, and a biochemical screening. The latter included analysis of serum for liver and kidney function parameters, determination of hepatitis A and B serology, and bile acid determinations on fasting and postprandial serum and urine specimens. Air and water from representative homes and urine from study participants were analyzed for selected organic compounds. The biochemical screening was conducted on two occasions 2 months apart. The initial hepatic profile testing revealed elevated concentrations of the serum enzymes, alkaline phosphatase and serum glutamic oxaloacetic transaminase, in residents who had used the contaminated water. During follow-up testing of these same persons 2 months later, these values were significantly reduced, as were postprandial serum concentrations of the bile acid of cholyglycine. Six individuals in the exposed group had slight hepatomegaly compared to one individual in the intermediate exposure group and none in the controls. Concentrations of carbon tetrachloride were as high as 18,700 μg/L in the well water samples. The biochemical and clinical observations are suggestive of a transitory liver injury probably related to exposure to the contaminated drinking water.

TOXIC WASTE DUMPS are a major source of environmental pollution in many areas of the country and are being recognized with increased frequency. In Hardeman County, Tennessee, wastes from a Memphis pesticide manufacturer have contaminated the groundwater aquifer serving approximately 60 nearby residents. During the years of operation, 1964–1972, an estimated 300,000 barrels of liquid and solid waste were buried in shallow trenches dug into the ridges at the 200-acre dump site. The dump was closed by state authorities in 1972 because contamination had been detected in test wells proximal to the burial areas.[1,2] The analyses performed at that time did not reveal any contamination in the three private water wells closest to the dump. During the fall of 1977, however, nearby residents became alarmed upon detection of unusual and unpleasant tastes and odors in their well water. Within a short time, the residents reported an unusually high number of symptoms including skin and eye irritation; weakness in the upper and lower extremities; upper respiratory infection; shortness of breath; and severe gastrointestinal symptoms, including nausea, diarrhea, and abdominal cramping. In general, these symptoms appeared to subside once ingestion of the contaminated water was stopped. A 1978 investigation by the U.S. Geological Survey confirmed the residents' observations that contamination of the local water supply aquifer had occurred[3] (Fig. 1). In an effort to determine the extent and possible etiology of the signs and symptoms of illness, a limited health screening study was conducted in November, 1978, when the U.S. Environmental Protection Agency strongly advised that all use of the water cease. The results from this study showed biochemical changes suggestive of liver injury in some of the residents whose water was contaminated. A second more extensive evaluation was conducted in January, 1979.

Fig. 1. Conceptual diagram of contaminant percolation below the disposal trenches.

Background. The Hardeman County toxic waste dump first came to our attention during the course of a seroepidemiologic research study of wastewater treatment plant personnel in Memphis, Tennessee, located approximately 60 miles from the dump site. One of the two treatment plants in this study served an area which included the pesticide manufacturer whose waste had formerly been deposited in the Hardeman County toxic waste dump. A portion of the wastes became airborne at the treatment plant because of the aeration process utilized, and because of the open basins that are generally used in such facilities. Workers complained of eye irritation and respiratory distress in the spring of 1978 during periods of time when chemical odors at the treatment plant were unusually intense. In conjunction with the ongoing study at the treatment plant, a urine screening study of the workers was conducted in May and June, 1978, and air samples were collected at various locations in the treatment plant. Hexachlorocyclopentadiene (HEX) and hexachlorobicycloheptadiene (HEX-BCH), two compounds produced by the pesticide manufacturer, were detected in air, wastewater, and urine specimens obtained at that time. In the June testing, workers at the Memphis North Treatment Plant had increased concentrations of the HEX-BCH compound in urine specimens collected late in the work shift compared to concentrations in urine specimens collected early in the work shift.[4]

By late 1978, the U.S. Environmental Protection Agency and the State of Tennessee Department of Health had detected more than 12 chlorinated organic compounds in the wells serving individuals living near the dump site.[5] Many of these chemicals (Table 1) are on the National Priority Pollutant Consent Decree List.[6] Carbon tetrachloride was the most abundant contaminant detected. Two of the other compounds in the dump are HEX and HEX-BCH.

Carbon tetrachloride, a highly toxic substance,[7,8] can be absorbed through the lungs, gastrointestinal tract, and skin; gastrointestinal and hepatorenal injuries are most prominent in poisoning from ingestion, and nervous system injuries predominate in inhalation poisoning. In all poisonings, the liver is the most drastically affected organ, but kidney injury may be more prominent clinically. A committee of the National Academy of Sciences–National Research Council has suggested that at a dose of 1 μg/day, a 5×10^{-8} lifetime risk of cancer exists.[7]

Among the most toxic chemicals known to have been dumped at the Hardeman County site are HEX and HEX-BCH. The occupational air standard[9] for HEX of 100 μg/m^3, much lower than that for carbon tetrachloride

($65,000 \mu g/m^3$), reflects that it is a much more toxic compound. Hexachlorocyclopentadiene is a potent irritant and is readily absorbed through the skin. Industrial workers often experience irritation of the eye and upper respiratory tract, and headache upon exposure to HEX vapors; burns result upon contact with the liquid. Animal studies have indicated that long-term exposures may result in a number of nonspecific adverse health effects.[10] No epidemiologic studies of workers who are occupationally exposed to HEX have been reported,[11,12] and there is no information available concerning the potential health effects resulting from chronic environmental exposure to HEX via contaminated air and/or water. Even less is known of the toxic effects of HEX-BCH, but there are indications that HEX-BCH may be as toxic as HEX.[13]

Populations studied. Sixty-one exposed individuals in 16 households along the Toone-Teague Road in Hardeman County, Tennessee, used water from wells containing carbon tetrachloride in concentrations exceeding 150 µg/L. Fifty-nine of these individuals participated in at least one of the health evaluations; 31 participated in both evaluations. An intermediate exposed group of 33 participants consisted of 8 individuals from two households along Toone-Teague Road whose wells contained up to 45 µg/L carbon tetrachloride and other people who were either close neighbors of or frequent visitors to families with contaminated wells. The location of the affected wells in relation to the dump site is shown in Figure 2. The "unexposed" control population was recruited from civic organizations and church groups elsewhere in Hardeman and adjacent counties.

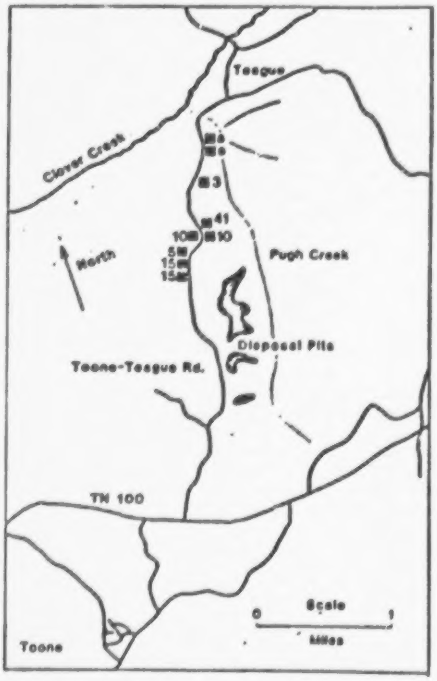
Fig. 2. Location of contaminated private wells near Hardeman County toxic waste dump (▪) and percent of exposed group using each well.



a. These wells were contaminated to a lesser degree and were used by two intermediate-exposed households.

Participants who had been occupationally exposed to pesticides (including those who worked at the dump site); who had consumed alcohol 24 hr prior to the collection of the blood specimens, or who regularly consumed in excess of 30 units of alcohol per month; or who had a history of a liver disorder were deleted from the analysis of data. The age and sex profile of the resulting exposed, intermediate exposed, and control groups is presented in Table 2.

METHODS

The protocol for the November, 1978, and January, 1979, health evaluations is outlined in Tables 9 and 10.

Many of the households had stopped consuming the contaminated water by May, 1978, and all apparently intended to heed the U.S. Environmental Protection Agency's advice (November, 1978) to stop all other uses of the water. The initial limited health screening was conducted in November, 1978, in an attempt to evaluate the residents while any physical or biochemical changes were still evident. Because of this limited time, and because of limited personnel, the study was designed to include: (1) analysis for selected organic compounds in air and water samples collected from some homes where wells were affected; (2) urinalysis for detection of selected organic chemicals; (3) blood analysis to determine liver profile and nonfasting serum bile acids; and (4) a questionnaire, including alcohol and drug intake, as well as past history of hepatitis or other liver abnormalities, to be administered by the public health nurses involved in the study. This study was conducted primarily to ascertain whether these chemicals, many of which are known hepatotoxins, were associated with liver dysfunction in the concentrations at which they were found, and to exclude other sources of liver disease.

The blood specimens were centrifuged and the serum was frozen and shipped to the Clinical Laboratory of Cincinnati General Hospital for performance of routine liver function determinations, including serum gamma glutamic transaminase (SGGT), serum glutamic oxaloacetic transaminase (SGOT), serum glutamic pyruvic transaminase (SGPT), alkaline phosphatase, and total bilirubin. Urine specimens and water samples were frozen immediately after collection and an aliquot of each was saturated with sodium chloride and extracted with an equal volume of petroleum ether. The petroleum ether extracts were stored in a freezer until time of analyses.

Air samples were collected using glass sampling tubes containing 150 mg of pre-extracted chromosorb 102 and desorbed with petroleum ether. All specimens were analyzed by electron capture gas chromatography using glass columns, packed with OV-101 or OV-17/QF-1, at 175°C, and were performed at the laboratories of the Department of Environmental Health at the University of Cincinnati, College of Medicine, Cincinnati, Ohio.

A follow-up study in January, 1979, included a more detailed questionnaire regarding past medical history, alcohol intake, drug consumption, history of hepatitis and other liver abnormalities, as well as a general health survey. In addition, experienced physicians conducted a blinded clinical examination to assess blood pressure, liver span (by percussion), and other physical parameters. While participants were fasting, serum and urine were obtained for determination of bile acids; liver and renal profiles and hepatitis serology were also performed. Postprandial serum and urine specimens were collected 2 hr after a breakfast of eggs, bacon or sausage, juice, toast, and coffee or milk, for analyses for bile acids.[14]

Representative air and water samples were collected from residences of the exposed, intermediate-exposed, and control groups. In some cases, indoor air samples were collected in bathrooms with either the bathtub or the shower tap running.

Statistical analysis included testing the dependent variables for normality and making transformations when necessary. Analysis of covariance was used to assess the effects of age, sex, monthly alcohol consumption, and their interactions on the dependent control variables. Adjustments were made for those covariables found to be significant. Analysis of variance was used to test whether significant differences between the exposed, intermediate-exposed, and control groups existed. When all three groups were tested simultaneously, analysis of variance with 2 degrees of freedom was used. Since this analysis involved multiple comparisons, the significance level was set at .02.

To test whether the individuals in the study group who were tested in both November, 1978, and January, 1979, showed a significant change in their hepatic profile and non-fasting serum bile acids, the differences between the results of the two periods were analyzed. A *t* test was then performed on the differences. Informed consent was

obtained from all study participants after the study procedures had been fully explained to them.

RESULTS

Water use. From May to December, 1978, a trailer-mounted water tank served as a temporary supply for kitchen and drinking uses for many residents. A second temporary supply, piped from an underground holding tank to a number of the residences, was installed in December, 1978. A permanent water supply from the village of Toone was connected to most of the residents in 1979. On the day blood and urine collection from Hardeman County resi-nts in November, 1978, many people in the affected area received certified letters from the U.S. Environmental Protection Agency (Region IV) advising them not to use their well water for any purposes because of high contamination with carbon tetrachloride. Some of the residents had stopped potable use of the water (i.e., drinking and cooking) beginning as early as the fall of 1977. A large group stopped use in May, 1978, after being advised by local public agencies that the water was unsafe. By August, 1978, practically all had ceased potable use of the contaminated water. Thus, any abnormalities reflected by the specimens collected in the November, 1978, survey would, for the most part, result from current exposure from washing and toilet uses, and prior exposure from drinking and cooking. By the time of the January, 1979, survey all uses of the contaminated water had ceased except for some use of contaminated water by two intermediate-exposed households.

Environmental monitoring. Detectable levels of HEX were found in the indoor air of three of the five exposed households examined in November, 1978 (Table 3). The highest concentration was 0.10 $\mu g/m^3$. Another related component, heptachlorobicycloheptene, was detected at 0.60 $\mu g/m^3$. Carbon tetrachloride was detected in all five homes and tetrachloroethylene in four of the five. In one of these homes two bathroom air samples were collected earlier in August, 1978: one sample with no water running nd the second with the shower on and the door closed. he concentration of carbon tetrachloride was 23 $\mu g/m^3$ in the first sample and 3600 $\mu g/m^3$ in the second. The higher value is approximately 5% of the American Conference of Governmental Industrial Hygienists (ACGIH) recommended occupational standard for workplace air.[9]

Sources of domestic water for the homes of the January, 1979, participants were analyzed. A summary of indoor and/or outdoor air and water samples collected from 37 homes are presented in Table 4. Water samples were designated as temporary (T), individual wells (I), and public (P). A temporary water supply was in use for all homes of exposed participants. Inside air samples were collected in the bathrooms with the shower or bathtub tap running. Water samples containing the highest concentrations of carbon tetrachloride and tetrachloroethylene were from the homes of exposed and intermediate-exposed participants. In general, samples from the control group had typical background levels.[15,16] Carbon tetrachloride and tetrachloroethylene were detected in most air samples, regardless of the group tested. Of the six control homes using a public water supply, one had an inside air sample containing more than 1 $\mu g/m^3$ carbon tetrachloride. Low levels of carbon tetrachloride (i.e., $\leq$ 1.1 $\mu g/L$) were detected in some routinely chlorinated public water supply samples. Individual private well samples, except those along Toone-Teague Road, did not contain detectable amounts of either compound.

Analysis of urine samples for selected organic compounds. Urine specimens collected from the exposed group in November, 1978, and from 137 participants from the three groups of participants in January, 1979, were screened for the presence of HEX, HEX-BCH, hexachlorobicycloheptene, chlordene, and heptachlor. No sample showed the presence of the selected chlorinated organics. A select group of nine individuals judged to have relatively high potential for exposure to carbon tetrachloride in January, 1979, were sampled for determination of carbon tetrachloride. Five of the nine persons were from the exposed group and four from the intermediate-exposed group. These intermediate-exposed participants included individuals who were using water containing about 50 $\mu g/L$ of carbon tetra-

*Samples were also analyzed for: hexachlorocyclopentadiene (HEX), hexachlorobicycloheptadiene (HEX-BCH), heptachlorobicycloheptene, chlordene, and heptachlor. Unless otherwise noted, none of these substances were detected.

†All numbers in parentheses represent the range.

‡Inside samples were collected in a bathroom with water running. Outside samples were collected within 10 m of the house.

§The types of water supplies in use were: T = temporary supply provided for homes with contaminated wells; I = individual wells; and P = public supply.

#One outside air sample also contained 3.2 µg/m³ of HEX-BCH.

∥This sample was obtained from a well known to be contaminated and thus no longer in use. The sample was also found to contain 2.5 µg/L HEX-BCH and 390 mg/L chloroform. The air sample, collected during and after water was drawn from the well, contained 0.6 µg/m³ HEX-BCH.

**NS = No sample obtained.

††Two indoor air samples also contained 4.6 and 1.5 µg/m³ of heptachlor.

chloride. No evidence was found for carbon tetrachloride in any of these urine specimens. These findings with human urine specimens are consistent with animal studies[17, 18] which show that (1) carbon tetrachloride administered to mammals is largely excreted through the lungs, (2) only a small fraction of absorbed material is metabolized, and (3) it is not excreted as the parent compound in the urine. It was, therefore, concluded that analysis of additional urine specimens for carbon tetrachloride was not warranted at that time.

Hepatitis serology. To determine if the results of the tests of liver function were due to a prior history of infection with hepatitis, antibodies to hepatitis A and B were determined. A log-linear model accounting for age was used to determine that the incidence of positive hepatitis serology was not significantly different between the groups.

Liver function tests. The results of the comparisons of the exposed group in November, 1978, and the controls are presented in Table 5. Significant differences were found for several of the tests; alkaline phosphatase and SGOT levels were significantly higher in the Hardeman County specimens ($P = .016$ and .010, respectively).

A comparison of the results for the 31 exposed individuals who were tested in both November, 1978, and January, 1979, showed a statistically significant change for all 4 variables with alkaline phosphatase, SGGT, SGPT, and SGOT—all decreasing from November, 1978, to January, 1979 (Table 6). No significant differences were detected between the results for any of the groups in January, 1979.

Renal function tests. Results of renal function tests were normal and showed no differences between the groups.

Bile acids. For 23 individuals in the exposed group, group bile acid determinations were made on non-fasting serum specimens collected in both November, 1978, and January, 1979. A comparison of the November, 1978, and January, 1979, results (Table 7) revealed that serum SLCC concentrations were significantly higher in November, 1978, than in January, 1979, suggesting a degree of hepato-

toxicity with resolution.

Results of analyses of fasting and non-fasting serum for specific bile acids—sulfated conjugates of lithocholate (SLCC) and cholyglycine (CG)—appear in Table 8. The mean non-fasting serum SLCC values were significantly lower in the exposed group than in the control. The clinical significance of this finding is unknown, since SLCC increases in most liver diseases; however, the lower levels may reflect a decrease in SLCC synthesis resulting from an enzyme inhibition.[19]

As expected, the mean change in SLCC and CG from the fasting to the non-fasting serum specimens was positive for all groups. The results of urine bile acid determinations were not different between the groups, except that the mean change in CG was negative for the exposed group and positive for the controls.

Medical histories. Medical questionnaires, which focused on illnesses during the 12-month period prior to the study, revealed that 11 Hardeman County residents were hospitalized. Complaints included gastrointestinal abnormalities, respiratory difficulties, neurological symptoms, muscular complaints, and high fever. Other individuals reported symptoms such as dizziness, headache, skin rashes, nausea and vomiting, numbness of limbs, and menstrual irregularities. During this same time period the only birth was a low birth weight infant with gastrochisis and eventration of intestines. Seven adults and five children reported vision problems. One individual in the control group had a severe myocardial infarction and was hospitalized. Another person in the control group had choroid retinitis.

Physical examination. One hundred eighteen individuals were examined: 48 in the exposed group, 24 in the intermediate-exposure group, and 46 controls. During physical examination, 7 individuals (6 exposed and 1 intermediate) had borderline liver enlargement (slight hepatomegaly). A significant difference between the groups was found ($P = .034$) using the Pearson chi-square test. No significant skin or eye abnormalities were detected.

DISCUSSION AND CONCLUSIONS

Concentrations of carbon tetrachloride, a suspected carcinogen, found in the contaminated well water of the

exposed group (median 1500 μg/L and maximum 18,700 μg/L) are considerably higher than the 2.6 μg/L level that has been proposed as a safe level for drinking water.[20] In comparison, the releases of carbon tetrachloride into the Ohio River in February, 1977, ranged only up to approximately 340 μg/L.[21] The highest concentrations of carbon tetrachloride found in air samples during this study were 326 μg/m³ in outside samples and 3600 μg/m³ in interior air. These concentrations are below the lowest concentrations in air that have produced toxic effects in man, 130,000 μg/m³.[7]

The highest concentration of HEX detected in the air of Hardeman County homes was 0.10 μg/m³–0.1% of the occupational standard.[9] In comparison, air levels at the Memphis North Treatment Plant ranged up to 39 and 278 μg/m³ for HEX and HEX-BCH, respectively. The highest concentration of HEX-BCH detected in this study was 3.2 μg/m³ in an outside air sample. In practice, when evaluating air exposure levels for two or more hazardous substances, their effects should be considered to be additive unless other information is available. This practice implies that for complex exposure situations, i.e., those that might be encountered with contamination of a groundwater supply and the air by a multi-component toxic dump leachate, determination of exposure levels of a single chemical may not adequately reflect the actual exposure burden experienced by an individual. In such case, consideration of the exposure levels of several substances is required.

Preliminary toxicity and mutagenicity testing[22] has shown that contamination of some well water samples was sufficient to cause a toxic response and, in one individual, a slight mutagenic response. Well water samples were tested for this biological activity without any concentration step in the laboratory procedure. Municipal drinking water from Cincinnati or New Orleans, for example, requires concentration of the organic components to elicit a biological response. Hexachlorobicycloheptadiene, reported to cause a mutagenic response in the Ames assay,[23] was detected in the contaminated well water, as were the suspected human carcinogens, chloroform and carbon tetrachloride.

The water sample collected from a heavily contaminated well in March, 1979, contained the highest concentration of carbon tetrachloride found in that area up to that time. This result indicates that contamination of the aquifer is increasing even with decreased overall local usage of the aquifer as a water supply. Future contamination of the much deeper artesian aquifer used at a location approximately 50 miles away by Memphis, Tennessee, is a distinct possibility through abandoned well shafts to this aquifer which could be plugged at the present time and, therefore, not detectable by the static head tests performed by the U.S. Geological Survey.[24]

Exposure to many agents, including drugs, alcohol, and a variety of chemicals, as well as disease states including viral hepatitis can cause liver damage. This study, which excluded these potential causes, indicated the presence of a subclinical and transitory liver injury that appears to be associated with the water consumption from wells contaminated by the leaching of material from the pesticide waste dump located in that area. The acute symptomatology and abnormal liver function tests have in all but a few cases returned to normal. However, it is impossible at this time to predict whether there will be any future chronic effects as a result of this exposure. Six of the seven individuals found to have enlarged livers were in the exposed group. A medical follow-up of those studied in this investigation is warranted.

REPORT ON THE FEASIBILITY OF ORGANIZING A STUDY TO ASSESS THE POTENTIAL HEALTH HAZARDS OF WASTE DISPOSAL SITES WITHIN THE UNITED STATES

Submitted by

UNIVERSITIES ASSOCIATED FOR RESEARCH AND EDUCATION

IN PATHOLOGY, INC.

June 22, 1983

UAREP, with technical assistance from the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB), has completed the feasibility study requested by CMA. A detailed report, presented in two parts, is submitted herewith. Part I describes the feasibility study, and Part II describes the proposed comprehensive review. We have concluded that within the time constraint of 10 months it is feasible to carry out a review of existing data and prepare a report covering the following general areas:

1. Prepare a list of the chemicals most likely to occur in a majority of waste disposal sites and which are most likely to create health hazards.

2. Identify the acute and, to a limited extent, the long-term toxic effects likely to result from human exposures to such chemicals. This would largely be based on published data in the peer review literature and make use of certain secondary sources of material available from industry as well as state and federal agencies.

3. Estimate the levels and duration of exposure to these chemicals at or above which toxic effects might be expected.

4. Identify those clinical and laboratory investigations which are likely to be most useful in detecting health effects in exposed populations and the epidemiological techniques to be utilized in so doing.

5. Develop scientific criteria for identifying immediate health hazards requiring urgent investigation or attention.

In carrying out such a review UAREP proposes to utilize a blue-ribbon panel of senior scientists and two special task forces assisted by professional and support staff.

We believe the review can be completed in 8 to 10 months, that adequate data is available and that the scientific and professional expertise necessary for organization of the panels, task forces, and staff can be obtained.

I. REPORT OF UAREP FEASIBILITY STUDY GROUP TO CMA ON THE POSSIBILITY OF ORGANIZING A STUDY TO ASSESS THE POTENTIAL HEALTH HAZARDS OF WASTE DISPOSAL SITES WITHIN THE UNITED STATES

A. INTRODUCTION

Public concern over the potential health hazards of waste disposal throughout the United States has reached a high level. The U.S. Congress and several state legislatures have enacted laws aimed at identifying hazardous sites and taking remedial action. Several thousand sites have been identified and the U.S. Environmental Protection Agency has designated that over 400 require "priority attention".

The problem of hazardous wastes has been the subject of considerable media coverage but the scientific documentation is more limited. Among the scientific publications are "Assessment of Health Effects at Chemical Disposal Sites" (Life Science and Public Policy Program of the Rockefeller University, 1981), and "Management of Hazardous Industrial Wastes: Research and Development Needs" (National Research Council, 1983). The former emphasizes the difficulties of making risk assessments in view of the complications involved in evaluating exposures. The latter reviews and makes certain recommendations regarding waste disposal and also recommends that "both public and environmental risks should be covered in a manner that allows comparison with existing risks that are acceptable to society," and that "an educational program be established to provide the public and industry with soundly based information on the options and risks that are acceptable to society" (page 14). The technical and practical problems of health effects on an individual basis are outlined in the study of the Love Canal (EPA, 1980) and, more recently, Heath (1983) has examined the epidemiology difficulties.

Whereas the National Research Council study does provide a certain consensus regarding the generic and practical issues involved in waste management, the nature and extent of health problems associated with waste disposal sites are much more controversial. Accordingly, though a small number of sites have been the subject of intensive study, the relevance and extent of these findings as related to the problem on a national scale is very uncertain and requires more intensive investigation.

In view of these facts and the delay in carrying out adequate in-depth studies of health effects on an individual waste disposal site basis and the need to obtain more factual information of potential health effects, the Chemical Manufacturers Association (CMA) concluded that it would be of value to all concerned if a group of knowledgeable and prestigious scientists would examine available scientific data and reach an interim conclusion regarding the nature and extent of health hazards which may exist at waste disposal sites as a basis for interim strategy and policy. Further, such a group would outline the scientific criteria for identifying potentially hazardous sites and indicate the methodology of investigation.

In March 1983, CMA entered into an agreement with Universities Associated for Research and Education in Pathology, Inc. (UAREP) to carry out a Feasibility Study to learn how and whether such aims might be achieved through the organization of a scientific review based on the expertise of the academic community.

B. SCOPE OF THE FEASIBILITY STUDY

A small group was set up within UAREP and the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB) to initiate the feasibility study. The goals of the group were (1) to determine what the aims and objectives of such a scientific study would be, i.e., health effects, exposures, etc.; (2) to determine how such a study would be organized and conducted; (3) to identify sources of information relative to (1) and (2) above; and (4) if possible, to identify what additional studies should be considered, if necessary. The group took into consideration the following areas as pertinent to the objectives of such a scientific review:

1. Information on i) the criteria of health effects to be used in evaluating endpoints of hazards, ii) the methodology of determining how such causal associations are to be determined, and iii) the extent and limitations of the universe of substances likely to be associated with waste disposal sites and their potential exposures for humans.

2. Identification of sources of data, as well as their relevance and potential significance in assessing health effects in waste disposal sites.

3. Information as to the availability of appropriate scientific experts in academia who might be available to participate in carrying out the study.

4. Information relevant to the organization of the interim study.

Initially, the Feasibility Study Group identified a number of parameters that might be addressed during the scientific review, including:

1. Determination of what inferences could be drawn from knowledge of hazardous chemical substances present in waste disposal sites and the probability of human exposures in relation to all types of health effects.

2. Identification of what inferences can be drawn regarding the effects of such substances based on other studies on humans or on animals, i.e., in environmental, occupational, or other settings, and included reports from existing waste disposal site studies. This also included the problem of assessing the limitations of epidemiology and other techniques in evaluating the effects of low level exposures to potential agents.

3. The possibility of carrying out preliminary correlation surveys based on i) known waste disposal sites, ii) studies on states known to have a high degree of environmental pollution, and iii) correlation studies based on general investigations in the U.S. in terms of pollution whether urban or rural, and involving air or water.

4. The possibility of the interim group establishing scientific criteria for identifying the existence of imminent health hazards in relation to chemical waste disposal sites and what would be the criteria or endpoints in terms of clinical and pathological data.

5. The possibility of the study group indicating further areas as requiring investigation in depth for the purpose of making the final reports more meaningful.

These various points were examined and an appropriate planning document prepared and circulated to a number of senior scientists as a background for discussion.

A number of experts representative of epidemiology, environmental waste disposal, toxicology, experimental biology, and biostatistics were approached (*see* Appendix I). In addition, a number of individuals in the field of experimental pathology and two representatives of environmental organizations were contacted. A considerable amount of effort was expended on contacting individuals within the Environmental Protection Agency (EPA) to determine the data and material available in its archives. The CMA advised UAREP/LSRO on contacts within the chemical industry; member companies of CMA prepared and submitted material for consideration by the Feasibility Study Group. Some individuals prepared reports and submitted them to UAREP/LSRO. Others were visited by members of the Feasibility Study Group or visited UAREP in Bethesda.

C. VIEWS OF EXPERTS

As anticipated, there was a wide range of opinions regarding the objectives and organization of any study relative to waste disposal sites. All were agreed on the inherent difficulties involved, but differed as to their importance in relation to an overall review. Some emphasized that if the problem was to be investigated, it should be done well or not at all. The majority agreed that, by far, the best way to investigate the overall problem was to carry out systematic examinations of individual sites. However, some experts also recognized the logistical difficulties associated with doing so in the immediate future, and concluded that some form of interim scientific evaluation of the extent and nature of the health problem was essential to provide some basis for rational public health policies and strategies in the next few years. For example, the Centers for Disease Control (CDC) have investigated only five sites in depth, although there is a considerable amount of material available on an additional twenty. All experts emphasized the fundamental importance of determining human exposures in relation to waste disposal sites, but none could offer exact guidance as to how this might be accomplished except through study of individual sites.

The point was raised by a number of individuals that in the past, few human health effects have been demonstrated to be caused by waste disposal sites and, therefore, it is probable that despite considerable efforts, little additional information may be obtained in future efforts of this type. If true, such a finding is clearly of importance in terms of future public health strategy and control of waste disposal sites since it suggests that more emphasis should be placed on methods of diminishing waste disposal, as done by the Japanese, than on the investigation and clean-up of existing sites. Many consultants indicated their doubt that the public will readily accept such a conclusion in view of preconceptions as to health hazards which have developed over the last several years and because of extensive media coverage of "crises". These aspects undergird the importance of ensuring the credibility of any study which carries out an overall investigation of this problem.

D. IDENTIFICATION OF POTENTIAL DATA SOURCES

The Feasibility Study Group discussed sources of data with the consultants and carried out preliminary surveys of the general literature. UAREP/LSRO staff members reviewed data retrieved from computerized literature services (Medline, Cancerline, Toxline, and Enviroline). They also reviewed such publications as the monograph series of the International Agency for Research on Cancer, and the Environmental Health Criteria documents of the World Health Organization on toxic hazards. In addition, a number of key articles were reviewed relative to the availability of specific material regarding waste disposal sites (*see* Appendix II). In brief, it can be stated that the amount of material available in the literature with respect to specific studies on hazardous waste disposal sites is very small. On the other hand, there are considerable data available regarding individual chemicals and their health effects based on a variety of studies including animal toxicology and epidemiology studies of occupational and other populations which might be of use for drawing inferences as to possible health effects.

There is a large amount of material available in the CDC on the potential health effects of waste disposal sites. Whereas some of it has been published in the general literature, the greater part is available as internal technical reports. However, the CDC staff indicated that this material would be made available to UAREP, and they would be pleased to collaborate directly with the UAREP study group in evaluating and identifying data pertinent to the overall problem. The experts at CDC were of the opinion that only waste disposal sites at Love Canal, New York; Triana, Alabama; Woburn, Massachusetts; and Times Beach, Missouri had been investigated adequately.

Key EPA personnel were contacted but little additional information seemed to be readily available regarding the problem, despite the fact that other experts indicated to the Feasibility Group that EPA has the best data on exposures. Several EPA contacts indicated that the desired information might be obtained from the CDC in Atlanta, but the CDC stated they had exposure data only for sites in which they had carried out some initial health investigations. CDC referred UAREP back to EPA. In conclusion, it proved impossible to identify who in EPA had such material; it was decided to await further approaches until after the organization of a review group.

Industry made material available to UAREP regarding exposures to suspected problem chemicals in the work place. A number of reprints and drafts of studies underway were made available to the Feasibility Study Group which were clearly pertinent and valuable in drawing inferences (*see* Appendix II). Key reference material is identified in Appendix III. In some cases these documents can be amplified by the literature in peer review journals. These data will be valuable and pertinent relative to information on the potential effects at specific exposure levels, but such data again raise the perennial question of how to deal with the effects of exposure at very low levels which would be fundamental to much of the assessment of the study group.

Preliminary contacts were made in the United Kingdom, and it would appear that within the European Common Market a considerable amount of data have been collected relative to hazardous waste disposal. Apparently, studies have also been carried out on potential health effects in some areas, but relatively little has been published. It is intended to investigate in further depth what material is available later this year, but preliminary investigations indicate that a number of individuals in Europe will be eager to collaborate in this context.

In conclusion, there appears to be less published data regarding the specific effects of waste disposal sites than had been originally anticipated. Although it is clear that much pertinent information is present in archives of various sorts, it will require a concerted effort to obtain and analyze this material. On the other hand, a considerable amount of published literature is available which contains important material on which inferences may be drawn by appropriate experts regarding potential health effects. The weakest area appears to be in relation to potential exposure levels. In this context, preliminary correlation studies may be of value. The Feasibility Study Group further explored what already had been done in this context.

1. Studies of Individual Waste Sites

While all agreed that a comprehensive study of individual waste disposal sites would be the most satisfactory rational method in identifying or excluding potential health effects, to do so would require extensive resources in manpower and expertise and a considerable period of time to implement. Clearly, it is exceedingly difficult to evaluate the potential danger of a waste disposal site unless accurate information, not only on the chemicals present but also on the probable degree of human exposure, is available. This suggests that for the study it will be necessary to draw up some general guidelines as to possible approaches. It will be highly desirable to explore what material is available within CDC in the form of internal reports in this context. CDC had considered but dropped the possibility of using certain chemicals as indicators of pollution. These CDC reports cover the PCB problem in the North Hollywood dump in Tennessee; the PBB problem in Michigan; the asbestos problem in Globe, Arizona; arsenic at Woburn, Massachusetts; and in a mixed deposit at Tar Creek, Kansas and Oklahoma. The reason many reports have not been published is that the data are essentially negative, far from complete and, therefore, "uninteresting". Thus, if relatively little evidence of exposure was found in a population group, no further action relative to health effects was undertaken. It would appear essential to explore further the importance of these negative findings as it may be fundamental to the objectives of the interim study to determine what are the conditions in which exposures are likely to occur and the period that may elapse before a site begins to break down and become a hazard. This will require further contact with appropriate experts in that area.

2. State Correlation Studies

Drs. R. S. Levine and D. Chitwood of the Department of Epidemiology and Public Health at the University of Miami prepared an "Analysis of Existing Data Pertaining to Potential Health Problems from Hazardous Wastes in Florida" in April 1983, acting under Prof. J. Davies. This was a rapid survey of the state of Florida covering areas of waste disposal sites and associated health indices in relation to such deposits. In general, no health effects were found in most areas of the state that could be definitively correlated with the EPA designated sites, although in some sites, there was a trend toward lowe. indices of health. However, in other areas of the state where pollution was known to be considerable, no health effects were evident. In fact, these often were the most healthful areas relative to the rest of the state and the U.S. as a whole. No definitive conclusions could be drawn on the health effects of such sites. On the other hand, Davies believes that such an approach can demonstrate that, while a health hazard due to a waste disposal site cannot be completely excluded, such studies can provide most useful data as to the probable existence and extent of the health problem. Interestingly enough, this Florida study indicated that an immense amount of material relative to existing sites had already been collected and was present in the State Department of Health. This suggests that in planning and investigating exposures, it may be desirable to use these sources in addition to EPA or CDC. *The Miami workers were convinced, therefore, that this approach did provide data of relevance and should be tried out in several other states*. They estimated that each such study could be carried out at a cost of approximately $100,000 within a three month frame utilizing the resources of local universities and departments of health. However, these costs may be unrealistically low because for the Florida study personnel, facilities, computers, and related equipment and materials were already in place.

The Feasibility Study Group felt that this approach should be explored further during the review as a potential source of data in carrying out future follow-up investigations to place some limits on the probable extent of the hazard.

E. FEASIBILITY STUDY RESULTS

1. Availability of Data

There is extensive literature available regarding the toxicology of many chemicals, but specific information relating to the amount of each chemical in individual waste disposal sites, the degree of population exposures, and the potential hazards involved are very limited. Thus, unless specific assumptions are made, the problem theoretically can be so huge as to defy analysis. Accordingly, it is estimated that the study will need to confine its review to a limited universe of chemicals, to drawing specific inferences that might be pertinent to the overall problem, and to defining and justifying such assumptions on a scientific basis.

2. Availability of Expert Consultants and Staff

Conversations with a number of experts disclosed a broad interest in toxic waste disposal problems and a willingness to participate in a scientific approach to solving these problems. Recruitment should not present a major problem although some desirable candidates will be unavailable due to other commitments or serious conflicts of interest.

A preliminary list of potential consultants is presented in Appendix IV. This list will be expanded as necessary in the course of the study, especially after the first meeting of the Executive Scientific Panel.

Based on previous experience, it was decided that resolution of problems such as conflict of interest and willingness to testify should not be attempted during the feasibility study but, rather, should await authorization to proceed with the comprehensive review.

F. CONCLUSIONS

1. The Feasibility Study Group concluded that it is both desirable and feasible to carry out a comprehensive review to evaluate the substantial body of available data for the purpose of permitting an interim conclusion as to the nature of the health problems likely to be associated with waste disposal sites. A detailed presentation of the Feasibility Study Group recommendations on the organization and implementation of the comprehensive review study follows (Part II). Such a study would have the following objectives:

i) Preparation of a universe of chemicals most likely to occur in waste disposal sites and which are most likely to create health hazards.

ii) The levels and duration of exposure to these chemicals above which toxic effects might be expected would probably have to depend largely on inferences. Thus, the perennial question of the presence or absence of low exposure level effects would require emphasis and standard methodological approaches. However, a considerable amount of material is available regarding water and air pollution within the U.S. which can be used in determining such possibilities. It will not be possible, however, to utilize all the material available within EPA and other institutions.

iii) Identification of the acute and, to a more limited extent, the long-term toxic effects likely to result from human exposures to such chemicals, and whether they are real or imagined. This review would be based principally on published data in the peer review literature. It would make considerable use of secondary sources of material in view of the great difficulty of evaluating the vast amount of primary and raw material in EPA or state archives, unless the latter had been adequately analyzed.

iv) Identification of those clinical and laboratory investigations which are likely to be most useful in detecting health effects in exposed populations and the epidemiological techniques to be utilized in so doing.

v) Development of scientific criteria for identifying an immediate health hazard requiring urgent investigation or attention.

A comprehensive review is considered desirable and feasible because it would be comparatively inexpensive in terms of money and manpower. While it will add relatively nothing new to the universal literature, it will provide a unique source of evaluated data for scientists and the public regarding the potential health hazards and scientific issues associated with investigating waste disposal sites. It will provide a mechanism whereby the scientific community can be directly involved in investigating such issues and correcting the misconceptions that are widely held by the public. It will identify problems that are likely to occur frequently and thus involve academia in a search for scientific rational solutions. This may be pertinent to the further development of more intensive studies on an individual waste disposal site basis which may be necessary over the next decade.

Such a review might be more credible if it had multiple sponsors and if it were perceived as an interim measure to be followed up by additional studies.

2. The Feasibility Study Group concluded that as the proposed review is being completed, it would be desirable to follow up with studies aimed at compiling and analyzing raw data in the files of EPA, CDC, and various states agencies, carrying out in other states procedures modeled after the Florida study, analyzing the NHANES II data bank and results of the Health Interview Surveys conducted by NCHS to develop baseline health values, and testing the validity of the criteria developed in the review in a limited number of specific toxic waste disposal sites.

Such follow-up studies would require participation of various agencies and organizations and should also be funded from a number of sources probably including government, industry, and private philanthropy. The follow-up studies would also require wider and more extensive involvement of the academic community in developing correlation studies and utilizing data from all sources, as well as more active involvement and cooperation between the academic community and CDC, as well as other government laboratories. In addition, follow-up studies would enhance the probability of producing new data and providing better baselines for developing new scientific and technological criteria for hazardous waste disposal.

The only major disadvantage associated with follow-up studies is the potential cost and the necessity for developing considerable manpower and resources in academia. On the other hand, these costs are likely to be relatively modest in the context of the vast expenses incurred in cleaning up waste disposal sites if this is not done on a rational basis.

II. FEASIBILITY STUDY GROUP RECOMMENDATIONS ON THE ORGANIZATION AND IMPLEMENTATION OF THE COMPREHENSIVE REVIEW STUDY

A. OBJECTIVES:

1. To prepare a list of the universe of chemicals associated with waste disposal sites which could prove hazardous to man as the result of excessive exposure. Identify, if possible, the levels of human exposures likely to occur in association with waste disposal sites.

2. To define the probable health effects likely to occur in association with waste disposal sites and classify these according to their nature, real or imagined, acute, subacute, chronic, or carcinogenic. This is to be based on inferences from the available studies within the literature and inferences drawn from occupational, animal toxicology, and other sources.

3. To identify the clinical and laboratory and results that should be utilized in investigating such problems, and the epidemiological criteria necessary to establish causal relationships. Special emphasis should be given to the evaluation of negative data in relation to low level exposures.

4. To identify the scientific criteria for describing a specific or individual waste disposal site as representing an imminent health hazard.

5. To decide to what extent these conclusions (#1-4) provide a basis for identifying which follow-up studies may be carried out.

B. IDENTIFICATION OF PROBLEM CHEMICALS AND THEIR EVALUATION

Crucial to the development of the study will be the establishment of guideline criteria for identifying the universe of substances in waste sites and for establishing causal associations between exposures and potential human health effects.

1. Universe of Substances and Waste Sites

For logistical reasons, the list of hazardous chemicals must be defined and limited but, at the same time, hazards of perceived potential major significance must not be excluded. Identification of such chemicals and their exposure levels will be fundamental to the success of the study because, above all, it will be necessary to review the effects of probable human exposures likely to occur, or to have occurred, in relation to hazardous waste disposal sites as a basis for any epidemiological approach.

In attempting to analyze the universe of hazardous substances, the following lists of chemicals have been examined during the Feasibility Study:

i) Chemicals identified in the Superfund Priority Sites list of 418 hazardous waste disposal sites. The list of chemicals was prepared by Dr. Blaine McKusick of du Pont.

ii) A list of chemicals provided by CMA and designated by six major chemical-producing companies as those considered to be the 20 most likely to cause risks or public perception of risk. Each company had prepared its own list of 20 problem chemicals. A few chemicals received five to six votes, but most received two or three, indicating that the interests of the six companies are not necessarily similar. However, the final list of 20 represents a consensus of the six chemical producers.

iii) A list of chemicals prepared for the State of California and published in Chemical and Engineering News 1982.

iv) EPA list of relative carcinogenic potencies among 53 chemicals evaluated by the Carcinogen Assessment Group (dated April 5, 1983.)

v) Other sources of material relating to general or local environmental pollution, such as the Love Canal list and lists provided by several consultants.

It is interesting to note that there is a certain degree of overlap among the chemicals on each of the lists mentioned above.

2. Evaluation of Exposures

Estimation of exposures are recognized to vary widely and, until now, no satisfactory methods of calculating these have apparently been developed. Thus, each waste disposal site must be investigated according to a highly systematic plan. The possibility, however, that an appropriate group will be able to provide guidelines for the development of appropriate models as to those chemicals most likely to pose a danger according to the construction, location and nature of a deposit will receive careful attention. Some attempt must be made to distinguish between waste disposal sites that are well constructed and likely to exist for a prolonged period, and those where there is evidence already of immediate breakdown and release. It is recognized that while air and direct exposures may occur, they are unlikely to present an important hazard and that greatest concern relates to potential water contamination and, possibly indirectly, through diet resulting from contamination of local vegetation.

Most important, the overall significance of small waste disposal sites must be examined. For example, these were believed to be the greatest problem in Florida. It will be necessary, therefore, to explore all these aspects of the problem and to ensure that the Executive Panel and two Task Forces contain experts who have had experience in movement of substances from sites. Thus, evidence in this area will depend on i) material from sites which have already been examined, ii) literature reports in this and other countries, iii) the availability of further material of the type that was obtained in Florida from local resources, and iv) other sources. It may be possible that, after reorganization, EPA may be able to provide further information to the study group than they have been able to provide to the Feasibility Group. An additional important source of information will be studies on wild and domestic animals in the region of the sites.

Considering the importance of this aspect of the total problem, the material available from known sites should be examined and analyzed first. Then, the possibility of developing a background database of the overall exposures in the general population of the U.S. relative to suspected compounds should be explored. What is known regarding excess exposures in different situations will be established and specific areas in which appropriate exposure studies should be conducted will be defined. Conversely, there may be sufficient material already in the literature to permit evaluation of the general effects (or lack thereof) at higher levels of exposure, but this, again, almost certainly will require review by a group of experts.

3. Evaluation of Health Effects

In view of the many potential chemicals involved, no attempt will be made to generate primary data or evaluate raw data unless it is absolutely essential. Thus, data on health effects will be predominantly generated from previous reviews or assessments available within the general literature and other pertinent sources which are available to the public. Some of the various aspects that can be studied include:

i) Health Effects

Health effects will be inferred from what is known regarding potential levels of exposure and inferences drawn from high, intermediate, and low levels of exposure in other situations. Any attempt to relate low exposure level health effects to the multitude of chemicals which may occur, not only in relation to waste disposal, without considering the general background of the United States will be difficult and require careful evaluation but must be done. Thus, some attempt may be necessary to develop a profile on what is already known regarding exposures of the human population within the U.S., in terms of tissue deposits, etc., and their significance in disease patterns. Much of this material may, in fact, be available within the literature and could be the subject of further in-depth evaluation.

ii) Acute Effects

It will be important to define end points that can be examined with relative ease because they are not dependent on prolonged latent periods. Such effects should be closely related temporally to exposures if they are significant. Therefore, acute health effects may be susceptible to review whether as indicated by clinical, or clinico/pathological, or biochemical examination. Investigations of acute health-effect criteria should be standardized to a certain extent; criteria should be established to distinguish between organic and psychosomatic lesions. In this context, inferences drawn from occupational, accidental, and similar exposures at higher levels will provide pertinent data.

A list of end points will have to be examined to determine which are most likely to provide information of importance in evaluating health effects related to waste site exposures. Such end points would include:

a) blood studies;
b) urinary studies;
c) analysis of breast milk and other fluids and tissues;
d) evidence of respiratory, kidney, liver and other dysfunctions;
e) evidence of damage to infants, such as congenital malformations, cytogenic abnormalities, etc.

iii) Chronic Effects

Chronic effects, notably cancer, will require careful evaluation in light of the associated long latent period. In view of the small number of individuals liable to be exposed in relation to a particular waste disposal site and considering the known carcinogenic effects to be anticipated from suspected chemicals, it is quite possible that no conclusions can be reached regarding negative or positive findings in this context.

iv) Teratogenic and Mutagenic Effects

Following exposure to suspected chemicals, teratogenic and mutagenic effects may occur rapidly and are identifiable through congenital malformations, but many limitations apply to interpretation of the significance of several tests for mutagenesis. The assistance of CDC can be very valuable in this respect; toxicologists and epidemiologists with special expertise will be required to evaluate the findings.

v) Baseline Data

To compare the health status of individuals exposed to waste disposal sites deposits with that of the general population of the U.S., baseline data are required. Data from the ongoing Health Interview Survey and the second National Health and Nutrition Examination Survey (NHANES II) 1976-80 carried out by the National Center for Health Statistics would be used to identify a basic health profile of the U.S. population. With this information in hand, it may be possible to determine, on a broad basis, whether any indices can be attributed to proximity to waste disposal sites for an exposed population.

vi) Experience in Japan and Europe

Direct contact will be made with appropriate scientists and experts in Europe and Japan, who will participate as consultants to the task forces.

vii) Studies on Flora and Other Markers of Toxicity

A review of data from wild and domestic animals will be made and evaluated in terms of their implications for human disease.

In conclusion, the Feasibility Group agreed that a vast amount of material was available on a national and international scale from which significant and important inferences could be drawn as to the probable nature and extent of ill-health effects that could be anticipated as a result of previous waste disposal practices. In the past this material has been scattered and considered usually in terms of individual chemicals. However, a number of studies have been carried out on air pollution. In contrast, studies on chemically polluted water -- probably the most feared result of waste disposal -- are very poor and in terms of human disease are essentially negative, although the importance of water as a major source of human exposure has been shown for many of the suspected chemicals.

The possibilities of such a review are probably greater than originally believed and further analysis will be of great value in terms of the involvement and understanding of the academic research community.

4. Epidemiological Studies

In view of the small numbers of individuals likely to be involved in most waste disposal site exposures, epidemiological studies will be difficult to perform and will provide little information in most cases. Thus, the comprehensive review will of necessity have to contain an evaluation of the problems and limitations inherent in assessments of health effects related to individual sites. In addition, other methodologies for collecting material on a wider scale will have to be explored.

This particular aspect of the problem will be the subject of a specific task force. In this context, it will be desirable to further explore the experience of the Miami group in Florida as a base for calculating the overall extent of the problem.

5. Identification of Scientific Criteria for Classifying a Waste Disposal Site as an Imminent Health Hazard

This will arise out of the general discussion in the early portions of the survey and be addressed later by the Executive Panel which may, however, wish to redirect the question to one of the Task Forces.

C. ORGANIZATION OF THE STUDY APPROACH

The comprehensive review study will require an Executive Scientific Panel (ESP), two Task Forces (TF1 and TF2) and a full time scientific and support staff secretariat. The ESP will consist of 12 to 15 eminent academic scientists of international reputation. The ESP will be multidisciplinary in membership, including epidemiology, pathology, toxicology, biostatistics, oncology, occupational carcinogenicity, industrial hygiene, biochemistry, public health, toxic waste engineering, and other closely allied fields.

TF1 will address the universe of chemicals and aspects of exposure. TF2 will concentrate on human health effects. Both Task Forces will focus on additional issues and individual problems identified by the ESP and call upon appropriate experts from all sources to provide information and evaluation of the technical and scientific problems inherent in the investigation. A preliminary list of scientists identified as potential candidates for the ESP and Task Forces is attached (see Appendix IV).

In view of the nature of the subject and its unusual political and scientific ramifications, it is difficult to give an immediate outline of the procedures to be adopted by the ESP. These will depend, to a certain extent, on organization of a compatible panel of experts and their preliminary review of the problems and resources available. Accordingly, this necessitates a flexible approach to the initial scientific analysis and structure; the procedures outlined below should not be taken as definitive. It is a general principle that every effort will be made to take cognizance of and acquire any scientific information from any source pertinent to the overall problem, and these data will be freely available at the conclusion. Further, members of the committee will avoid obvious conflicts of interest. Lastly, adequate disciplinary representation and expertise should be included among the members to ensure wide exploration of all scientific viewpoints and to ensure credence in both the academic and public domain.

1. Management and Organizational Procedures (ESP)

While procedures must remain flexible, there are several aspects common to all evaluation studies. These include the following:

i) Preliminary conferences are held with key individuals to explore extant knowledge concerning hazardous waste disposal sites and to further identify experts with access to additional information.

ii) The purpose of these preliminary conferences is not only to identify additional individuals who may have pertinent knowledge or are engaged in research in related relevant topics, but also to define those scientific activities which may be most closely related to the particular type of evaluation. These discussions are used to generate a list of individuals as well as a list of key words to be used in computerized literature searching. Subsequent identification of key review articles and important information sources provide further expansion of the lists of potential consultants and pertinent key words.

iii) A definitive listing of pertinent parameters to be examined by the Executive Committee and Task Forces is prepared as appropriate based on an expanded review of current literature by the staff, current information on other aspects related to scientific evaluation, and consultation with key individuals concerning the scientists identified initially. In this case, care is taken to select all potentially pertinent information which will be balanced by the inclusion of work of investigators involved in related topic areas, or scientists holding divergent views concerning the subject.

iv) Typically, at this point a working paper will be prepared for the ESP by the professional scientific secretariat. This working paper describes the background of the issue and the extent of information available concerning the study topic. These papers, along with selected references, are sent to each participant prior to the ESP meeting at which the subject will be discussed.

v) Experience suggests that discussions with individual investigators or knowledgeable persons, as well as deliberations of the ESP at one to three-day meetings, coupled with a comprehensive literature review and analysis by the Task Forces, constitutes a reasonable basis for drafting an evaluation study. This draft report is prepared by the secretariat based on information obtained from the Task Forces, scientific literature, and from the discussions of the ESP. The draft report reflects documentation from the scientific literature and other valid information sources, as well as pertinent analysis and opinions of the Task Force members and/or ESP members. Where a controversial area exists, all aspects are discussed in considerable detail, and scientific references are given wherever possible. In instances where a consensus opinion of the ESP cannot be derived, an effort is made to include all divergent views.

vi) Drafts on individual topics are submitted to all members of the ESP as appropriate and, on occasion, to additional experts for their critical review and comment. Revision of the draft report is made by the staff based upon comments and emendations submitted by all participating consultants. The final draft may be resubmitted to the ESP for subsequent review and concurrence.

vii) The report of the ESP will be submitted to the UAREP Board for review and approval. This secondary review process ensures that the report will meet acceptable standards for scientific objectivity and fulfillment of study objectives.

viii) The Final Report will be published *in toto* and a synopsis will be published in the scientific literature.

2. Management and Organizational Procedures (TF)

The two Task Forces will be organized and will operate in an analogous manner, with certain exceptions. First, the ESP will play a major role in identifying qualified experts for membership on the two Task Forces. Second, membership on the Task Forces will be based primarily on scientific and disciplinary expertise with less emphasis on international reputation and possible conflict of interest.

Task Force reports, or series of reports, will be considered internal documents and will be exchanged between Task Forces, but delivered to the ESP. Task Forces are also considered ad hoc and may change in membership as determined by the ESP and secretariat. At least two ESP members will be on each Task Force.

3. Procedures to Assure the Adequate Identification as well as the Quality, Relevance, and Completeness of Data

Once specific problem areas have been identified relative to the universe of substances, exposure routes, health effects, etc., the ESP or a steering group of the ESP will explore i) information concerning a particular chemical, ii) toxic effects, and iii) identification of appropriate experts for consultation by the ESP for appointment to TF1 or TF2. Where appropriate, staff will visit investigators at their laboratories. The process of identifying and evaluating pertinent information will continue throughout the evaluation process, but it will probably not be possible to utilize sources of unanalyzed raw data.

Quality, relevance, and completeness of scientific data are a critical aspect of scientific evaluation. Experience dictates that the quality of data is related to the completeness of data and where these data may be found. In the final analysis, a reasoned judgment of the quality, relevance, and completeness of available data is a matter of a determination by the members of the ESP. The validity of the determination rests with the experience and reputation of the individuals who are selected to serve on TF1 and TF2, as well as with those on the ESP.

4. Elimination of Potential Bias and Conflicts of Interest Among Members of the ESP and TF1 and TF2

Evaluation studies of this type must use guidelines that include ad hoc self-terminating approaches, emphasis on the minimization of bias, and avoidance of quasi-permanent committees and appearance of vested interest. The following steps and techniques have proven successful in maximizing the objectivity of the input to evaluation studies:

i) Key individuals assist in the identification of potential ESP members and TF participants. These include members of the UAREP Board and other representatives of scientific societies who are able to identify knowledgeable scientists with expertise in particular study topics. The multiplicity of input provides ample opportunity to identify a wide diversity of potential participants. Every effort is directed towards balancing potential participants by the inclusion of consultants who may hold divergent views on a particular topic.

ii) In the course of developing an intensive literature database, it is possible to identify the specific contributions of potential participants to the study. Quality and objectivity of scholarly publications as well as reputation are evaluated by the project's staff.

iii) The final lists of ESP and TF members are reviewed by the UAREP Board. This review procedure is included to eliminate bias and potentially avoid vested interests following which an effort is made to informally contact each individual a second time to invite him or her to participate in the study.

iv) ESP and TF members are asked to complete a conflict of interest form. This form provides information on the extent of financial obligations and involvement in the public and private sectors which may bear upon the particular topic under evaluation. Procedures have been developed for maintaining the confidentiality of these statements; and an internal review is conducted by members of the UAREP Board. Specifically, the Executive Officer of UAREP, the President of UAREP, and the Business Manager of UAREP reviews each statement of conflict of interest for evidence of potential conflict. Where no conflict exists, forms are signed, sealed, and held until completion of the project. Where potential conflict is noted, the opinion of legal counsel is sought.

If and when conflict of interest is apparent, the scientist is informed, while a decision is made as to whether or not he or she should be given further consideration. If in the affirmative, the individual must agree prior to the evaluation study that, if at any point this conflict of interest is raised by the Executive Officer of UAREP or the project director, he or she would state for the meeting record non-participation in the deliberations or decision-making process of the Task Force or ESP.

5. Procedures to Resolve Conflicting Opinions

During Task Force meetings or during the deliberations of the ESP, the respective chairmen will ensure informal, harmonious discussions in which all participants are allowed to present data and comment on information presented. The chairmen must be selected for their experience in this context. Draft reports, revisions, and preparation of the final reports by the secretariat are written to reflect opinions of participating scientists and other knowledgeable individuals, documentation from the scientific literature, and pertinent analysis. Because the staff rapporteurs are recognized as professional scientists by all, the credibility of the document is further enhanced. Every effort is made to present and document divergent views, but to give a consensus of scientific opinion where appropriate. If a consensus is not appropriate, then divergent views are documented as completely and objectively as possible.

In cases where minority opinions are necessary, they are written by the secretariat based upon discussions with those dissenting members. Members with dissenting opinions are asked to indicate their identity and their concurrence with the material that has been independently prepared by the staff. This aspect is further strengthened by the subsequent secondary review and approval of the report by the UAREP Board.

6. Proposed Study Plan

The overall study comprises specific steps as follows:

Month 1: Identify Executive Scientific Panel and Chairperson

The ESP will be comprised primarily of members of the academic community with expertise in epidemiology, toxicology, biostatistics, experimental pathology, oncology, occupational carcinogenesis, industrial hygiene, biochemistry, public health, and toxic waste engineering. Emphasis will be placed upon obtaining the cooperation of individuals from the academic community who, insofar as possible, have no conflicts of interest or biases. These will be individuals recognized for their expertise in the particular relevant disciplines. There will be approximately 12-15 individuals on the Executive Panel. Budgetary considerations are based on a 15-member Executive Panel and five two-day meetings (or some combination of 10 days of meeting time).

One of the first individuals to be identified would be the Chairperson of the ESP. This individual should be available 100% of the time during the study period and should be recognized for his or her general expertise in review and evaluation of public health and scientific issues, rather than only for expertise in one particular discipline. Because most knowledgeable scientists in industry and government have *ipso facto* a conflict of interest, an effort will be made to recruit academic members of the scientific and medical community as ESP members.

Nominations will be accepted from all sources, including public announcements and specific requests to various communities concerned with toxic waste sites, such as industry, government, environmentalists, academic scientists, scientific societies, professional organizations, and other sources (e.g., the National Academy of Sciences, Carnegie Mellon Foundation, Ford Foundation, etc.). *The primary criteria for membership on the Panel will be scientific expertise and freedom from conflict of interest or bias.*

A list of potential invitees as members of the ESP will be prepared by the staff and forwarded to the UAREP Board for concurrence and selection. Individuals selected will be asked to serve on the Panel and to complete the conflict of interest information.

Months 2-3: Initial ESP Meeting

A two-day meeting for organizational purposes will be conducted. Prior to this Panel meeting, all members will have been invited and informed of the conditions of the appointment and the scope of the study. In addition, they will receive a working paper describing the project and an agenda for the meeting. At the meeting, the consultants will be asked to:

i) review and concur with the study plan or make modifications as they deem desirable,

ii) identify the need for Task Force activities and to provide a scope of work for those Task Forces, and

iii) identify individuals to serve on the several Task Forces.

It should be noted that at least two members of the ESP will serve on each Task Force as chairperson and vice chairperson (or recorder or rapporteur). Members of the Task Forces will be selected on the basis of scientific expertise and may include representatives of industry, government, academia, and other communities as required by the scope of Task Force activities.

Months 3-4: Appointment of the Task Forces

At the present time, we believe that only two Task Forces will be necessary.

Universe of Chemicals and Human Exposures Task Force (Task Force #1): The first activity of Task Force #1 (TF1) will be to evaluate the several lists of chemicals that describe the universe of substances found in hazardous waste disposal sites, and to finalize a finite list of substances likely to prove problematic in terms of hazardous waste disposal sites. It should be noted that at this stage, TF1 may require additional outside expertise from both government and industry as consultants.

The second activity of TF1 will be to examine information available on the substances in the finalized universe of chemicals, and to identify levels of probable exposure, methods or route of exposure, and duration of exposures that may prove to have some impact on human or animal health, and on the environment. TF1 will have seven to nine members and may utilize an additional five consultants. TF1 will meet four times for two days each.

Health Effects Task Force (Task Force #2): TF2 will consist of nine to eleven persons and will provide guidance in the evaluation of probable health effects that are to be anticipated in relation to hazardous waste disposal exposures of those chemicals within the universe of substances that have been determined to be potential exposure problems.

TF2 will consider acute and chronic health effects that are likely end points of exposure, information available from previous epidemiological studies and from occupational medicine, scientific evaluation of toxicity in laboratory animal studies, and data from other waste disposal sites. TF2 may wish to organize itself into subgroups. Additionally, it is expected that TF2 will require a greater input from staff in terms of literature and data analysis. TF2 may also require more time and meetings than TF1. TF2 will meet five times for two days each.

Months 3-6: Meetings of Task Forces

It is anticipated that TF1 must meet first and that TF2's progress will be dependent upon the output from TF1. The budget reflects a total of six meetings for the two Task Forces; however, it is anticipated that TF1 would meet twice and TF #2 would meet four times. Both TF1 and TF2 would draft reports, with the reports of TF1 being submitted to TF2.

The final output from TF1 would be a finalised list of problem chemicals, and information concerning environmental, animal, and human exposures that may prove to have demonstrable health effects. Emphasis would be upon human health effects. Clearly, this background information would be essential for TF2 in categorizing the likely end points or criteria for human health hazards and in identifying sources of data where the Health Effects Task Force would look for information relative to the toxic effects and potential health effects of the substances.

Months 4-7: ESP Meeting

Following the completion of the reviews of TF1 and TF2 and the completion of their draft reports, the ESP would utilize this information to create a draft of the review study report.

The conclusions of the review study draft report would point out what should be looked for in any waste disposal situation based upon extant scientific knowledge concerning the potential hazard to man, rather than upon political expedience, public complaints, or other reasons. A strong case would be developed for a reasoned judgment on scientific evidence of potential risk. The Tentative Final Report of the ESP would be published and made publicly available for comment.

Month 8: Open Public Forum

After publication of the Tentative Final Report of the ESP, an opportunity would be provided for all members of the public and the several communities of interested parties to come and address, either in writing or orally, the ESP at an Open Public Forum. The topic for discussion would be a review of and comments on the Draft Report in terms of garnering opinion as to the approach being presented and identification of any additional needs or deficiencies. This open public forum would be recorded and a transcript of the entire forum would be made available at cost to all participants. The ESP would be seated in front of the room and would listen to and accept all comments. The purpose of the Open Public Forum is information gathering and there would be no emphasis on entering into a dialogue or presenting the information in an adversarial manner. The organization and conduct of the open forum would be disseminated as widely as possible. In making arrangements for this, those individuals who wish to testify orally would be asked to provide written statements. Those not wishing to testify orally would be given deadlines for submission of written material. By negotiation, all oral testimony would be confined to a finite period of time.

Months 9-10: Review of Information Received

The ESP would meet a third time to discuss all information presented at the Open Public Forum and to revise as necessary the Tentative Final Draft of the Report. Based upon the decisions reached by the ESP in a review of the included comments, an attempt would be made to reach a consensus by the panel and a Final Report would be prepared. This Final Report would be provided to the sponser of the study and would be disseminated widely and made available at cost to the public.

D. ESTIMATION OF COSTS

In analyzing the necessity of input from Task Forces and ESP, and to provide adequate time for review of the information collected by Task Forces, for preparation of Task Force reports, and for subsequent analysis of this information by the ESP and preparation of the Final ESP Report, as well as a desire to have informed public input, it seems logistically necessary to provide for a minimum of a 10-month period for the Comprehensive Review Study. The budget has been developed on the basis of 10 months. The budget also contains additional information concerning the number of meeting days for members of the Task Forces and panel.

COMPREHENSIVE REVIEW STUDY

10-Month Budget

	Annual Salary Basis	10-Month Budget	
Personnel[a]			
Project Director[b]	$ 62,400		
Staff Scientists[c] (2)	101,400		
Associate Scientists[d] (2)	58,800		
Administrative Assistant	24,953		
Technical Data Analyst	19,394		
Technical Literature Specialist	19,394		
Senior Secretary	17,958		
Clerk	12,226		
Subtotal	$316,525	$263,771	
Fringe Benefits & Payroll Taxes @ 28%		73,856	
Subtotal Personnel			$337,627
Consultants[a]			
a) Executive Scientific Panel 15 members @ $500/day 5 meetings - 2 days each		75,000	
b) Task Force #1 9 members @ $450/day 4 meetings - 2 days each		32,400	
c) Task Force #2 11 members @ $450/day 5 meetings - 2 days each		49,500	
Subtotal			$156,900

Travel and Per diem[f]		
Travel @ $600; per diem @ $100		
a) Executive Scientific Panel		
5x15x600	45,000	
5x2x15x100	15,000	
b) Task Force #1		
4x9x600	21,600	
4x2x9x100	7,200	
c) Task Force #2		
5x11x600	33,000	
5x11x2x100	11,000	
Subtotal		$132,800
Other Direct Costs[g]		
Telephone @ $600/month	5,400	
Postage and mailing (includes overnight mail) @ $975/month	8,775	
Expendible supplies	3,600	
Computerized literature retrieval @ $240/month	2,160	
Word processing @ $320/month	2,880	
Report preparation (2TF + 1 tentative + 1 final) 4 reports @ 150 pp. each @ $27/p., 550 cc.	16,200	
Duplication & photocopying, est. 216,000 @.07/p.	15,120	
Open public forum:[h]		
Hall rental for 2 days	1,100	
Transcript preparation	2,350	
Conference center expenses[i]		
1 meeting - 4 days	2,400	
Miscellaneous	975	
Subtotal		$ 60,960
TOTAL DIRECT COSTS		$688,287
INDIRECT COSTS[j]		
(39.6% of salaries, wages and consultant fees = $494,527)		$195,833
TOTAL COSTS		$884,120
FIXED FEE @ 10%		88,412
TOTAL CONTRACT		$972,532

BUDGET NOTES

a) All personnel are 100% FTE for 10-month period. It is essential that scientific staff be full time; some salary lapse with support staff may occur during months #1 and #10, but wage figures are not adjusted.

b) The Project Director would be a senior scientist (M.D. and/or Ph.D.) whose international reputation and scientific credentials are impeccable. His or her expertise would be in toxicology, pathology, and epidemiology.

c) Staff Scientists (2) would be mid-level M.D. or Ph.D. investigators with at least 10 years of professional experience and relevant education. Each would be initially assigned to a Task Force as staff coordinator. Staff scientists would be responsible to the Project Director and would play a major role in data collection and analysis, and preparation of reports.

d) Two M.S. or B.S. level associate scientists with at least 3-5 years experience in data analysis and review, as well as skills in scientific writing.

e) Consultant fees are based on the mid-point of daily fees paid by government contracts and private industry. Fees are necessary to attract and hold the most highly qualified persons as well as the necessity to require that they contribute substantially to the ESP and Task Force reports. Fees for ESP members are based on $500/day and those for Task Force members, $450/day. The budget assumes expert consultants from industry or government (as appropriate) would receive no compensation from UAREP.

f) $600 per trip is based on the average travel cost experience of UAREP and LSRO for 1982-83. Per diem is based on the daily rates for the Marriott Hotel, Bethesda, rate plus $24.00 per day.

g) Estimates derived from current projects and previous contractual activities of analogous scope and size.

h) Based on $550 per day (local Bethesda hotel rate).

i) One ESP meeting may be a four-day meeting outside the Bethesda area.

j) UAREP Indirect Cost rate at 39.6% estimated for 1983-84. Rate is based on total direct personnel salaries, wages, and consultant fees.

APPENDIX I

List of Persons and Organizations Consulted in the Feasibility Study

Patricia A. Buffler, Ph.D.
Associate Dean for Research and
Associate Professor of Epidemiology
University of Texas
Health Science Center at Houston
P.O. Box 20186
Houston, Texas 77025

Glyn G. Caldwell, M.D.
Deputy Director
Chronic Diseases Division
Center for Environmental Health
Centers for Disease Control
Atlanta, Georgia 30333

Philip Cole, M.D.
Professor and Head
Department of Epidemiology
and Biometry
University of Alabama
Tidwell Hall, Room 203
University Station
Birmingham, Alabama 35294

Morton Corn, Ph.D.
Johns Hopkins University
School of Hygiene and Public Health
615 North Wolfe Street
Baltimore, Maryland 21205

John E. Davies, M.D., M.P.H.
Chairman, Department of
Epidemiology and Public Health
University of Miami
School of Medicine
Medical Arts Building, Rm. 100
1550 N.W. 10th Avenue
Miami, Florida 33101

Perry J. Gehring, D.V.M., Ph.D.
Vice President of Agricultural
Products R&D
Director of Health and
Environmental Sciences
Dow Chemical U.S.A.
Bennett Building
2030 Dow Center
Midland, Michigan 48640

Joe W. Grisham, M.D., Ph.D.
Professor and Chairman
Department of Pathology
University of North Carolina
School of Medicine
Chapel Hill, North Carolina 27514

Clark Heath, M.D.
Director
Chronic Diseases Division
Center for Environmental Health
Centers for Disease Control
Atlanta, Georgia 30333

David G. Hoel, Ph.D.
Biometry and Risk Assessment Program
National Institute of Environmental
Health Sciences
P.O. Box 12233
Research Triangle Park, NC 27709

Irving Kessler, M.D.
Department of Epidemiology
and Preventive Medicine
University of Maryland
School of Medicine

APPENDIX II

Literature and Reference Material
Reviewed by UAREP/LSRO in the
Feasibility Study
(March - May 1983)

100 - 199

Memoranda (originating outside FASEB)

File No.	From	Subject	Date
100	McKusick, B.	Potentially hazardous chemicals at disposal sites	12/1/82
101	McKusick, B.	Superfund priority sites	1/7/83
102	McKusick, B.	Corn Report (file #500)	1/4/83
103	Foege, W.	Transmits CDC report on long-term followups of populations exposed to toxic hazards, #506	6/21/82
104	Tozzi, J., OMB	Toxic Torts -- evaluating merits of alternative legislative proposals (sent by T. O'Leary, CMA)	4/18/83

CMA Literature File

200 - 299

Letters (Incoming)

File no.	From	To	Subject	Date
200.0	Umland, C., Exxon	Karrh, B., du Pont	CDC's Superfund Responsibilities	12/22/82
200.1	Umland, C.	Endicott, K.	Transmits draft of on-going study (file #550(a),(b))	3/28/83
201	Karrh, B., du Pont	Zoll, D., CMA	Transmits summary of mortality study of chemical workers (file #620)	1/21/83
202	Thomas, L., Sloan-Ket.	Gov. Carey, New York	Transmits Love Canal report (file #505)	10/8/80
203.0	McKusick, B.	Higginson, J.	Transmits study summaries (file #204, 441(b), and 609)	3/16/83
203.1	Mckusick, B.	Higginson, J.	Transmits Contra Costa study (file #509)	3/16/83
203.2	McKusick, B.	Higginson, J.	Transmits summary of Contra Costa study (file #510)	2/28/83
203.3	McKusick, B.	Higginson, J.	Transmits study summaries (file #611-618)	3/16/83
203.4	McKusick, B.	Higginson, J.	Transmits Triana summary (#1017) & article on CA waste rules (#812)	4/13/83
204	Senger, J., Monsanto	Karrh, B., du Pont	Contains study summaries. (Enclosure to letter #203.0)	1/3/83
205	Parker, H. Union Carb.	McKusick, B du Pont	Transmits 2 studies on petrochemical workers (#440 & 441)	3/15/83
206	O'Leary, T., CMA	Higginson, J.	Transmits lists of banned chemicals from CFR (file #1013 & 1014), from EPA (file #1015), and CO_2 study (file #437)	4/19/83
207	Duchie, W., Shell Oil	Higginson, J.	Transmits 7 documents on McColl Site, California, file #519-525	4/13/83

Letters (Cont'd.)

File no.	From	To	Subject	Date
208	Gaffey, W.R., Monsanto Co.	Altman, P.	Transmits reprints (#445-447) and paper (#529) on 2,4,5 T production accident in W. Va.	4/20/83
209	Cole, P., U. of Alabama	Higginson, J.	Response to Dr. Endicott's letter of 4/5/83 on Feasibility Study	4/20/83
210	Gehring, P.J., Dow Chemical	Endicott, K.	Same as for #209	4/21/83
211	O'Leary, T.F., CMA	Endicott, K.	Transmits an OMB memo on toxic torts, file #104	4/22/83
212	Kissell, R.G., du Pont	Altman, P.	Transmits 2 letters from Kissel to CMA Superfund Task Group, file #213 and 214	4/28/83
213	Kissell, R.G., du Pont	CMA Superfund Task Group	EPA Expenditure Status	3/15/83
214	Kissell, R.G., du Pont	CMA Superfund Task Group	Analysis of Proposed National Priority List	2/16/83
215	Dourson, M.L., EPA	Altman, P.	Transmits EPA Document Listing, file #1018	4/29/83
216	Silbergeld, E., Env. Def. Fund	Fisher, K.	Response to UAREP letter of 4/5/83 on Feasibility Study	5/3/83
217	Levine, R.S., U. of Miami	Higginson, J.	Transmits report on hazardous wastes in Florida, and a summary, file #532(a) & (b)	4/28/83
218	Damstra, T., NIEHS	Fisher, K.	Transmits 3 lists of chemicals found in Superfund sites, file #1037 - 1038	5/11/83
219	Buffler, P.A., U. of Texas	Higginson, J.	Comments on Feasibility Study strategy	5/16/83
220	Paulson; Lundy, Audubon Society	Endicott, K.	Response to UAREP letter of 4/5/83 on Feasibility Study	5/17/83
221	Heath, C.W. CDC, Atlanta	Higginson, J.	Inquiried if further input was required of him for waste study	6/5/83

Angiosarcoma of Liver in the Manufacture of Polyvinyl Chloride

Three reported cases of angiosarcoma of the liver serve as an alert to the probability that this condition may, in some instances, be causally related to employment in the manufacture of polyvinyl chloride resins.

J. L. Creech, Jr., M.D. and M. N. Johnson, M.D.

On January 22-23, 1974, a manufacturer of polyvinyl chloride and copolymers notified its employees, the National Institute of Occupational Safety and Health, the Kentucky State Department of Labor, and the public that three workers had died of angiosarcomas of the liver. These cases had as a common denominator employment in the manufacture of polyvinyl chloride resins.

A patient of one of the authors (J.L.C., Jr.) died on September 27, 1971 from an angiosarcoma of the liver. At that time the potential causal relation to the manufacture of polyvinyl chloride resins was not realized. Although other clinical manifestations of exposure to VCM were known (acroosteolysis), only one experimental paper[1] indicated that vinyl chloride may be a carcinogen. The tumors in rats that he described occurred primarily in the skin and were epidermoid in origin.

Eighteen months later on March 3, 1973, a second former employee in the Louisville plant died. Since he was not under our care, no connection was made that the two cases may have had a common origin. When a third patient died on December 19, 1973, the pathologist on gross examination diagnosed an angiosarcoma of the liver. Since all three patients were treated by different physicians, no relationship to exposure to polyvinyl chloride was surmised until the authors, recognizing the rarity of the tumor, and learning that all three had worked in the PVC plant, brought the matter to the attention of the company. Further search indicates that a fourth death from angiosarcoma may have occurred five years earlier (1968), but the death certificate shows primary liver tumor as the cause of death. (Clinical, epidemiologic, toxicological and occupational investigations are being vigorously pursued with regard to other employees who may have been similarly exposed.)

A brief resume of the first case under our care is presented. The history, clinical course, and pathologic findings are consistent with the others who died of angiosarcoma. These cases will be presented in a group and in more detail at a future date.

Case Report

Patient one, a 36-year-old white male, was hospitalized January 5, 1970 because of tarry stools.

Occupational History. — The patient had been employed from November 1955 until his illness, except for two lay-offs of nine months in 1958 and six months in 1959, as a chemical helper and operator in the Louisville plant of B. F. Goodrich Chemical Company in the manufacture of polyvinyl chloride resins.

Present Illness. — At the time of admission the patient had no complaints except passage of tarry stools. Past history was negative except for an operation for hemorrhoids four years earlier. Physical examination showed pallor, and black stool on rectal examination. Liver and spleen were not palpable. Although upper G.I. series was interpreted as normal, a tentative diagnosis was made of bleeding duodenal ulcer.

On diet and medication, the patient had no recurrence of

Dr. Creech is Plant Physician, The B.F. Goodrich Chemical Company, Louisville, Ky. Dr. Johnson is Director of Environmental Health, The B.F. Goodrich Company, Akron, Ohio.

Reprint requests to Dept. 0620, Bldg. 51-H, 500 South Main St., Akron, Ohio 44318 (Dr. Johnson).

overt bleeding until May 1, 1970, four months later, when he was readmitted for tarry stools. Again he was found to have marked pallor, and tarry stool on rectal examination. At this time the liver was demonstrably enlarged and the spleen was palpable. Blood chemistry studies (SMA 12) were not significantly abnormal: total bilirubin, alkaline phosphatase, LDH and SGOT were only slightly elevated. G.I. series showed only anterior displacement of the stomach, but barium swallow suggested esophageal varices. Intravenous pyelogram was normal; barium enema was normal except for displacement of the splenic flexure by an enlarged spleen. Liver scan on May 4, 1970 was interpreted as being compatible with a large lesion in the left lobe of the liver, extending into the right lobe.

Operative Procedure and Findings. — On May 7, 1970 an exploratory laparotomy was carried out. Under anesthesia the abdomen was entered through a vertical incision. Marked enlargement of the liver and spleen were noted, and the liver was adherent to the anterior surface of the stomach. The liver capsule was quite thickened and tough. There was a gelatinous-like material at the junction of the liver and the stomach. Retroperitoneal nodes were very soft, enlarged, and succulent in appearance. A biopsy of the liver was performed. There was marked degree of hemorrhage following this which was controlled with large sutures through the liver.

Report of Pathologic Findings

Gross. — Specimen is a portion of soft gray and light brown tissue that is 2.2 x 3.9 x 1 cms. at the present state. In some areas it appears to be composed of liver and in others light beige, moderately firm tissue with areas of sponginess and softness.

Microscopic. — Most of the tissue pattern of liver is replaced by luxuriantly growing cells forming irregular spaces. These spaces display many trabeculations in their lumina and are lined by pleomorphic malignant endothelial cells. Here and there these cells grow in nearly solid sheets. Elsewhere they line capillaries. There is a newly formed stroma with various degrees of hyalinization here and there.

Diagnosis. — "Liver, biopsy of, angiosarcoma (malignant hemangioendothelioma)."

Clinical Course

Following the laparotomy and biopsy the patient was given 4000 R cobalt and several intra-arterial infusions of 5-FU. During this time there was marked distortion of his blood chemistry with severe diminution of albumin and marked increase in total bilirubin, alkaline phosphatase, LDH and SGOT. After a stormy course and several months of convalescence, including several abdominal paracenteses for recurrent ascites, he recovered sufficiently to return to work for a short time. He succumbed to the liver tumor fourteen months post-operatively and died on September 27, 1971.

Special Communication

Editor's Note

Professor Cesare Maltoni, Director of the Institute of Oncology of the University of Bologna, Italy, presented the results of his unpublished experiments with vinyl chloride on February 15, 1974 at the U.S. Dept. of Labor hearing in Washington, D.C. on "Possible Hazards of Vinyl Chloride Manufacture and Use". His work, which is obviously original and innovative, demonstrated angiosarcoma of the liver and other tumors in experimental animals at air concentrations of vinyl chloride which are known to be present at times in workroom atmospheres. Professor Maltoni describes his methodology as predictive of the carcinogenic potential of airborne chemical contaminants. Professor Maltoni is apparently the first to show the relationship between exposure to vinyl chloride and the appearance of angiosarcoma in mammals.

Mortality Study of Workers in the Manufacture of Vinyl Chloride and its Polymers*

Irving R. Tabershaw, M.D. and William R. Gaffey, Ph.D.

Animal studies have shown that inhalation of vinyl chloride produces in rats angiosarcoma of the liver as well as cancers of the lung, kidney, skin and other sites. Although workers in occupations involving exposure to vinyl chloride have been found to have an increased risk of hemangiosarcoma, no excess of other cancers has so far been reported.

This historical prospective mortality study of 8384 men who had at least one year of occupational exposure to vinyl chloride before December 31, 1972, demonstrated that cancers of the digestive system (primarily angiosarcoma), respiratory system, brain, and cancers of unknown site, as well as lymphomas, occurred more often than expected in those members of the study population with the greatest estimated exposure. The mortality from other cancers was lower than that of the general male population, with the exception of cancers of the buccal cavity and pharynx. There was an excess of these cancers, which however was inversely related to estimated exposure. The explanation for the latter finding is not apparent.

The other major findings of the study are: (1) The overall mortality of the study population was approximately 75% of what would be expected in a comparable population of U.S. males. (2) No cause of death showed a statistically significant excess over what would be expected in a comparable U.S. male population; and (3) No deaths identified as angiosarcoma of the liver were found other than those previously identified.

This is the first epidemiological study which suggests that in humans vinyl chloride may also be associated with cancer of multiple sites.

Drs. Tabershaw and Gaffey are from Tabershaw-Cooper Associates, Inc., Suite 808, 6000 Executive Blvd, Rockville, MD 20852.

*The research on which this report is based was supported by a group of companies engaged in the synthesis and/or the polymerization of vinyl chloride and administered in their behalf by the Manufacturing Chemists Association.

Vinyl chloride in its manufacture and polymerization has been identified as a narcotizing agent[1] as a liver toxin,[2,3] and as a vasospastic agent producing a specific occupational disease, acroosteolysis.[4] Recently, vinyl chloride has been incriminated as a carcinogen producing in a group of workers engaged in the manufacture of polyvinyl chloride a rare fatal liver tumor, hemangiosarcoma.[5] Large doses of the chemical in rats reportedly produced cancer of the skin, lung and other organs.[6] Unpublished but public information[7] indicates that inhalation experiments with rats in doses easily reached in manufacturing operations produces in addition to angiosarcoma of the liver, skin, kidney and other malignant lesions.

The present study, however, was not restricted to the conditions and sites suggested by the above investigations, but concerned itself with the entire spectrum of causes of death, to the extent permitted by the size of the study group. The objectives of the study were: (1) To compare the mortality of individuals who have worked in vinyl chloride plants with that of the general population, (2) To compare mortality patterns within the population of vinyl chloride workers, based upon estimated occupational exposure, and (3) To compare mortality among vinyl chloride workers with the mortality of other occupational groups.

The study population consisted of individuals from 33 plants who had worked for at least one year in a job involving exposure to vinyl chloride before December 31, 1972, and included retired and terminated as well as active workers. For each such worker the date of birth and an employment history were obtained, and the vital status of the worker as of December 31, 1972, was ascertained. For those found to have died, those death certificates that were available were obtained and the cause of death determined. The observed mortality was compared with that of the United States male population.

Data Collection

In each plant, data were collected for each worker stated by the plant management to have been employed for at least one year in a job involving exposure to vinyl chloride. In some plants, particularly those producing the monomer, this determination could be made on the basis of job titles. Usually, however, exposure was a function of both job title and the location of the job in the plant, so that the assessment of exposure had to be made on a case-by-case basis by plant officials.

Data were collected for as far back in time as complete records were kept. In most cases this covered the entire history of the plant. In others, records were kept for a fixed period such as a decade. In a few, records were kept for different periods, depending on whether the worker had died on the job or had left employment.

In most plants it was impossible to quantify exposure. However, industrial hygiene and safety personnel in each plant were able to identify certain jobs and locations as involving the highest exposures in the plant, and to classify other exposures as medium or low relative to the "high" represented by the jobs with the greatest exposure. Consequently, each exposed job in a worker's history was scored 1, 2 or 3 to indicate low, medium or high estimated exposure.

This gross classification has two major failings as a result of the subjective nature of the estimates. The first is that the scores represent estimated relative exposure within a given plant. It is therefore possible that in objective terms, a "high" score in one plant corresponds to a "medium" or even "low" score in another. The second is that the scores usually do not take into account changes in exposure over time. A worker with long service may therefore have had jobs in the remote past which involved "low" exposure relative to other jobs at that time, but which might be "high" in comparison with current exposures in the same job. This subjective classification is therefore of questionable validity in characterizing the exposure of a given worker. For epidemiological purposes, however, those who have high scores can reasonably be expected, on the average, to have had the greatest exposure, while those with low scores will have had the least, even though the true exposure in each group may vary considerably from person to person.

The estimated exposure history of each worker was summarized by calculating an Exposure Index (EI). This was done by multiplying the number of months on each job by the exposure score, totalling these over all exposed jobs, and dividing by the total number of months of exposure.

Follow-up of Study Population

A follow-up procedure was instituted for those who had left employment and whose vital status could not be determined at the local plant, using direct mail follow-up and retail credit bureau investigations. Table 1 shows the vital status of the population as of December 31, 1972. Follow-up is 85% complete. Those who were not found were born (and began their exposure) about ten years before the group on which follow-up was complete, and had about half the duration of employment in exposed jobs with a slightly higher EI. Although there appears to be nothing very unusual about this group in terms of work history and exposure, it is nevertheless true that their exposures took place further back in time than that of the group successfully traced. It is therefore possible that their mortality, after a substantial latent period, might show a somewhat different pattern from that of the traced group.

All of the subsequent analysis is concerned with the 7128 workers on whom follow-up was complete. Table 2 shows their distribution by duration of exposed employment and the year in which that employment began. Although almost half the study group first entered exposed employment in 1960 or later, there are nevertheless 854 workers with 20 years or more exposure, and 1640 with 15 years or more. Table 3 shows the relationship between duration of exposure and EI. There does not appear to be a close relationship between the EI

Table 1. — Follow-up Status of 8384 Vinyl Chloride Workers.

	Total	Alive	Dead	Unknown	Death Certificates	
					Rec'd	Not Rec'd
Number	8384	6776	352	1256	328	24
Percent	100.0	80.8	4.2	15.0	92.7	7.3

and the duration of exposure, that is workers with a higher EI do not differ substantially in duration of exposure from those with a lower EI. One implication is that in assessing the relationship between mortality and exposure both duration and level of exposure can be examined separately as well as in combination.

Calculation of Risk of Death

The risk of death is expressed as a Standardized Mortality Ratio (SMR), which is the ratio of the number of observed deaths in the study population to the number of deaths to be expected in a comparable population of U.S. males. SMR's were calculated for overall mortality and for 33 major cause groups.

Table 4 shows observed and expected deaths, and the SMR, for each of these causes for the total study group. In calculating the SMR's for specific causes, the 24 deaths for which no certificates were found were assumed to have the same cause distribution as those for which certificates were available.

In the standard population each SMR would be equal to 100. Therefore the statistical significance of the deviation of each SMR in the study population from the expected value of 100 was tested.[8] A single dagger indicates those SMR's which differed significantly from 100 at the 5% level, that is, which had a probability of .05 or less of occurring by chance. A double dagger indicates those which were significant at the 1% level. SMR's based on fewer than five observed cases were not tested for significance.

Table 5 shows the same SMR's for workers with an Exposure Index below 1.5 versus those at 1.5 or above. The dividing point of 1.5 represents a level halfway between "low" and "medium."

Table 6 shows similar results for workers with less than five years exposure versus those with five years or more.

In order to examine the possible interaction between duration and level of exposure, the study population was divided into four groups on the basis of both EI (low vs high) and duration of exposure (short vs long) using the same dichotomization as Tables 5 and 6.

Table 7 shows the results for short versus long exposure in the low EI group, and Table 8 shows the same comparison in the high EI group.

In each of the above tables, deaths for which certificates had not been received were assumed to be distributed as a uniform percentage of all causes. The cause specific SMR's were therefore adjusted upward by a percentage which varied in each subgroup.

Results of Analysis

The overall mortality of the study population is statistically significantly lower than that of the U.S. male population. There were 352 observed deaths compared with 467 expected, for an SMR of 75.

Table 4 shows that no specific cause of death was statistically significantly greater than expected. Several, particularly heart disease, accidents and "other diseases" not detailed in the tables, were significantly below their expected values.

When the study population is divided according to intensity and duration of exposure (Tables 5 and 6) and combinations of these measurements (Tables 7 and 8) three major patterns emerge.

For malignant neoplasms as a whole, the SMR increases with increasing exposure, whether measured by level, duration, or both. In the high exposure group with 5 years or more exposure (Table 8) there are 36 observed cases and 26.11 expected.

For cardiovascular — renal diseases as a group, there are also increases in the SMR with increasing exposure, but the numbers of observed cases remain less than expected, the differences being statistically significant in all groups except the high exposure, long duration group in Table 8.

For all other causes, there are no consistent relationships with exposure.

Within the malignant neoplasms, the largest (although not statistically) significant SMR is in cancers of the buccal cavity and pharynx, with five observed, 2.84 expected, and an SMR of 189. However, Tables 5 to 8 show that all these cases have Exposure Indexes below 1.5 and four out of the five have less than five years exposure. Table 10 is a listing of these deaths with age at death, duration of exposure, and cause as stated on the death certificate.

Cancer of the digestive system shows

no excess in the study population as a whole. However, in those workers with an EI of 1.5 or higher, there are 12 observed cases where 9.14 are expected (Table 5). In the subgroup of the above workers with five years or more exposure, there are 11 observed cases and 7.47 expected.

Respiratory cancer shows a slight excess in the total group, and a similar pattern for different exposure categories, with 13 observed versus 10.28 expected when the Exposure Index is 1.5 or higher, and 12 observed versus 8.50 expected when, in addition, the duration of exposure is five years or more.

Malignant neoplasms of other and unspecified sites show an excess in the total group, and an increase with both level and duration of exposure (Tables 5 and 6). The relationship with exposure is more pronounced, since those with exposures of less than five years have fewer cases than expected.

The lymphomas, although occurring at about the expected rate when the whole group is considered, are concentrated almost entirely in the high exposure, long duration group. In that category there are four cases observed and 1.84 expected.

Cancers of the genital and urinary organs, and leukemia, have fewer cases than expected. The number of cases is too small to examine any trends.

Discussion

The favorable overall mortality of the study population is a phenomenon commonly observed in working populations. Standardized Mortality Ratios in the low 80's and below have been found.[9,10] Even in occupations with well defined hazards which cause an increased risk from a specific cause, the overall mortality may still be favorable because of the low risk from other major causes of death, frequently in the cardiovascular — renal category.[11]

*SMR's adjusted for deaths with cause unknown

†Significant at 5% level

‡Significant at 1% level

In view of these facts, SMR's which are higher than expected may be worthy of attention even if they are not statistically significant. This is especially true in the present study since the number of deaths from many causes is quite small, and even a relatively high SMR may not reach statistical significance.

If, in addition, a particular cause shows a consistent pattern of increase with exposure or estimated exposure, the findings are particularly interesting.

By these criteria, mortality from digestive cancer, respiratory cancer, cancer of other and unspecified sites, and lymphomas, appear to be related to exposure as defined in this study.

In view of the association between vinyl chloride exposure and angiosarcoma of the liver, the digestive cancers were examined further to see what contribution angiosarcoma made to the observed mortality pattern.

Of the 19 digestive cancers, seven were liver cancers, of which two were angiosarcomas according to the death certificate. However, among angiosarcoma deaths in vinyl chloride workers identified by other investigators, there were six which occurred in the present study population during the study period. They were all found in the course of the study. Table 11 shows these cases with the cause of death as given on the death certificate. Note that one case was certified as cirrhosis, and was so considered throughout this study, since the validity of comparisons with population data required that cause of death be determined only from information on the death certificate. The other five were correctly classified as

liver cancer but only two were specified as angiosarcoma.

If there had been no angiosarcomas, the number of deaths classified as cirrhosis in this study would have decreased by one and the number classified as digestive cancer would have decreased by five. The pattern of duration and intensity of exposure in these five cases was such that if they had not been present there would have been no relationship between exposure and digestive cancer. The mortality pattern in this cause group is therefore attributable to angiosarcomas of the liver.

The other cause group worth further investigation is cancer of other and unspecified sites, both because it is a heterogeneous category and because it seems, unlike the other cancers, to be more related to duration than to level of exposures.

Table 9 shows a list of the specific causes included in this category, which is essentially brain cancer and generalized cancer with primary site unknown. About 40% of the observed deaths were due to brain cancer. In the general male population, about 22% of this category is due to brain cancer, so that not only is the mortality from cancer of other and unspecified sites excessive, but brain cancer is overrepresented within the category.

The possibility exists based on the lack of specificity of some of the listed causes that some of the brain cancers were not primary, but metastases from another unidentified site such as the lung.

The cancers of the buccal cavity and pharynx are difficult to explain because of their occurrence in the low exposure, short exposure group. It is possible that this is a chance occurrence, that exposures to other substances were involved, or that the mouth and pharynx may be peculiarly susceptible because of the gaseous nature of the chemical.

Possible Biases in the Calculation of Risk

There are two major potential sources of bias in the study. The first is that the follow-up rate is lower than is desirable. The second is that observations of workers with long exposures followed by a long latent period are not adequately represented so that the power of the study to detect causes of death associated with long exposure and long latency is impaired. Populations with such characteristics exist and should be investigated.

Table 10 — Malignant Neoplasms of Buccal Cavity and Pharynx (140-148, I.C.D.) in VCM Epidemiology Study Population

Respiratory cancer in relation to occupational exposures among retired asbestos workers[1]

PHILIP ENTERLINE, PIERRE DE COUFLE[2], and VIVIAN HENDERSON
Department of Biostatistics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Enterline, P., de Coufle, P., and Henderson, V. (1973). *British Journal of Industrial Medicine*, **30**, 162-166. **Respiratory cancer in relation to occupational exposures among retired asbestos workers.** A cohort of 1 348 men who completed their working lifetime in the asbestos industry and retired with an industry pension during the period 1941-67 was observed through 1969 for deaths. The average length of employment in the asbestos industry for these men was 25 years and all had exposures to asbestos dust. In some instances these exposures were very high and continued for many years. Mortality for this cohort of men after age 65 was 14·7% higher than for the entire population of United States white men living at the same ages and time periods. This excess was due almost entirely to cancer and respiratory disease. The cancer excess was chiefly due to respiratory cancer where mortality was 2·7 times the expected. The respiratory disease excess was entirely due to asbestosis.

A time-weighted measure of asbestos dust exposure at the time of retirement was calculated for each man. This was made up of the summed products of dust levels for each job (expressed in mppcf) and years at each level. This measure was directly related to the respiratory cancer excess at ages 65 and over, ranging from 1·7 times expected for men with less than 125 mppcf-years exposure to 5·6 times expected for men with 750 or more mppcf-years exposure. There appeared to be no direct relationship between asbestos dust exposure and respiratory cancer below 125 mppcf-years. Important increments in respiratory cancer mortality apparently occurred somewhere between 100 and 200 mppcf-years exposure.

Separation of the effects of time from the effects of average dust level on respiratory cancer mortality showed that the contribution of each was about the same and that a time-weighted measure of asbestos dust appears to be an appropriate method for predicting respiratory cancer effects.

There are relatively few studies on the dose-response relationship between asbestos dust and respiratory cancer. In a recent article McDonald *et al* (1971) reported on the incidence of respiratory cancer deaths among Canadian asbestos miners in relation to their cumulative asbestos dust exposure. That study suggests that a definite dose-response relationship exists and that below certain measurable levels of asbestos dust there appears to be little or no carcinogenic response. Three earlier studies also suggested a dose-response relationship. Knox, Holmes, Doll, and Hill (1968) found, in a preliminary report, that after dust controls were introduced in a British asbestos textile plant during the 1930s, the incidence of respiratory cancer fell from a 10-fold excess to a rate similar to that in the general population. Newhouse

[1] A revision of a paper read on 9 February 1972 at the Annual Meeting of the American Academy of Occupational Medicine, Pittsburgh, Pennsylvania, U.S.A.

[2] Currently with the US National Institute of Occupational Safety and Health.

(1969) reported that workers with heavy asbestos dust exposure had an excess of respiratory cancer, whereas those exposed to moderate or light doses had no excess. In a study which compared three segments of the American asbestos industry, Enterline and Kendrick (1967) reported that the estimated levels of asbestos dust related directly to variations in respiratory cancer deaths and to asbestosis deaths.

This is a report on the mortality experiences at ages 65 and over of a group of men who completed their working lifetime as production or maintenance employees in the asbestos industry, who retired with an industry pension, and who were all exposed to asbestos dust in varying degrees in the course of their employment. The average duration of employment in the asbestos industry was 25 years with a range from 3 to 51 years. Historic dust levels were sometimes in excess of 50 million particles per cubic foot of air. For each of these retirees it was possible, by combining personnel records with asbestos dust level estimates for each job and time period, to reconstruct their asbestos dust exposure history and, for each man, to assign a measure of his cumulative asbestos dust exposure at the time of retirement.

The cohort upon which this study is based consisted of all men retiring during the years 1941-67 and deaths occurring among these men through 1969. Such a study could be conducted almost entirely using industry records, except that where deaths occurred official copies of death certificates needed to be obtained. Included in this study were three kinds of retirees — those who retired normally at age 65; those who retired before age 65 for personal reasons but lived to age 65; and men who retired before age 65 because of a disability but who lived to be 65. The observed mortality among these men was compared with an expected mortality based upon the experience of the entire US white male population living in the time-age intervals that characterized the retired population. Inclusion of disabled retirees improves comparability with the US white male population as the latter also includes men unable to work for health reasons. The modified life table method was used for computing the expected number of deaths. This method is widely used and has been described in detail in an earlier report (Enterline, 1965).

There was a total of 1 376 men in this study who reached age 65. Of these, complete exposure and job histories were available for 1 348. Dust levels at each job site and time period were expressed as million particles per cubic foot of air (mppcf). It was not possible to estimate very precisely the dust level for each job, particularly for past periods, and dust levels could be only roughly classified. Jobs were placed in one of six classes or ranges, and for calculating total exposure mid-points of the range were used. Classes used were: no exposure (0); under 5 mppcf (2·5); 5-10 mppcf (7·5); 10-30 mppcf (20·0); 30-50 mppcf (40·0); 50 mppcf or more (62·5).

To compute total dust exposure for each man the dust level at each job and time period was multiplied by years at that job and summed across all jobs. This total cumulative exposure can be thought of as mppcf-years. Thus, if a man with a 30-year work history initially worked 10 years at a job with a dust level at that time of 20·0 mppcf, 10 years at a dust level of 2·5 mppcf, and 10 years at a dust level of 7·5 mppcf his total exposure would be: (10 × 20) + (10 × 2·5) + (10 × 7·5) or 300 mppcf-years. His average exposure level would be 10 mppcf.

Results

Table 1 shows observed and expected deaths and standardized mortality ratios (SMR) for selected causes of death for the entire cohort of 1 348 men for whom complete job and exposure data could be obtained. The expected value of the SMR, where observed and expected deaths is the same, is 100, and deviations from 100 are percentage deviations from expected mortality. As noted above, expected deaths were based upon the mortality experience of the entire US white male population living at the same ages and time periods as the cohort under study. Of the 754 deaths observed, death certificates could be located for 733. It is not known how much SMRs for individual causes of death might be changed were the remaining 21 death certificates available. It is unlikely, however, that there would be much of an increase for any single cause and no attempt has been made to allocate these 21 deaths to cause of death groupings. All death certificates were coded according to the Seventh Revision of the International

Classification of Diseases by a regular coder from the US National Center for Health Statistics. Numbers in parentheses in Table 1 correspond to the International Statistical Classification rubrics.

Table 1 shows that those men who retired from an industry with asbestos dust exposure had an overall mortality rate 14·7% higher than all US males. This excess is due almost entirely to cancer and disease of the respiratory system. For cancer, the greatest excess is in cancer of the respiratory system (ISC 162, 163) but with some excess also in cancer of the digestive system and other cancers. For respiratory disease the excess is due entirely to pneumoconiosis and pulmonary fibrosis. Eighteen of these deaths were due to asbestosis (ISC 523.2).

Data shown in Table 1 are very similar to data from other studies of asbestos workers which included men at ages under 65 (McDonald *et al.*, 1971; Enterline and Kendrick, 1967; Selikoff, Churg and Hammond, 1964; Mancuso and Coulter, 1963; Doll, 1955; Elwood, Cochrane, Benjamin, and Seys-Prosser, 1964). The excess in cancer, and particularly respiratory cancer and digestive cancer, and respiratory disease reported in other studies shows up quite clearly in this population of retired males. This is important since it could be argued that by age 65 men susceptible to an occupational hazard may already have been selected out of a cohort by death, and any effects of occupational exposure could not be detected.

In the analysis which follows only the relationship between asbestos dust exposure and respiratory cancer will be shown. Parallel analyses could, of course, be made for other causes of death.

Table 2 shows the relationship between total dose expressed as mppcf-years and mortality from respiratory cancer. For each dose interval actual means are shown in parentheses. It is quite clear that total dust exposure is highly related to respiratory cancer. If these data are plotted on arithmetic paper this relationship appears to be linear except at the highest dose level.

Of particular interest is the SMR of 166·7 for the 533 men with a total exposure of less than 125 mppcf-years. For a man with 25 years work in the asbestos industry this represents work, on average, at or below the old threshold limit value (TLV) of 5 mppcf. Table 3 divides the 533 men with a total mppcf-years under 125 into three total dust groupings to see if any relationship between dust and respiratory cancer exists within the under 125 mppcf-years' category. As in Table 2, actual means for each dose interval are shown in parentheses. No direct relationship between dust and respiratory cancer excess appears. In fact the relationship appears to be slightly inverse. Whether the SMR for

TABLE 3

Observed and Expected Deaths and SMR for Respiratory Cancer (ISC 162-163), 533 Men with Total Dust Exposure below 125 mppcf-yr, Retiring from the Asbestos Industry 1941-67 and Followed Through 1969

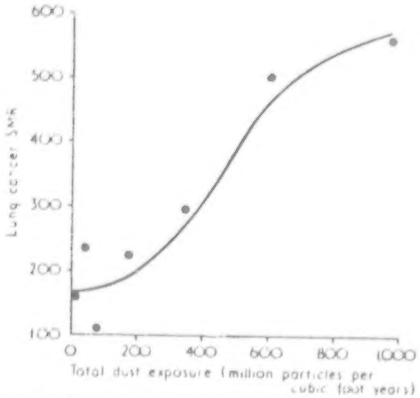
Total dust exposure (mppcf/yr)	*No. of men*	*Respiratory cancer deaths*		
		Observed	*Expected*	*SMR*
Under 25·0 (11·1)	75	2	1·3	153·8
25·0-62·4 (44·4)	181	8	3·1	258·1
62·5-124·9 (89·1)	277	5	4·6	108·7

espiratory cancer of 166·7 for men in the lowest xposure category is related to asbestos dust or to omething else cannot definitely be established from hese data. One of the factors that probably elevates omewhat this SMR is the fact that the men in this tudy were mainly urban dwellers and respiratory ancer death rates are normally higher in urban than n non-urban areas. Thus, since the expected number f deaths is based on the entire United States it may e too low. Correction for this for men with total sbestos dust exposures under 125 mppcf-years educes the SMR for this group of men to 146·2. ata published by Haenszel, Loveland and Sirken 1962) for the year 1958 were used to make this orrection.

Some additional help in evaluating the SMR of 166·7 for men with total dust exposures of under 125 mppcf-years also comes from a completely arallel study of 324 male retirees who worked as roduction or maintenance employees in the manuacture of a variety of building materials and were xposed to some dust, none of which contained sbestos or any substance suspected as being carcinoenic. Nine of these men died of respiratory cancer ISC 162, 163) as compared with 5·3 expected, giving n SMR of 169·8.

The Figure combines data from Tables 2 and 3 and stimates the relationship between total asbestos dust xposure and respiratory cancer. Superimposed on he Figure is a freehand drawing of cumulative ormal distribution—a distribution frequently used s a model for dose-response relationships.

If an SMR for cancer of the respiratory system of round 150 can be considered not excessive for men ho spent most of their working life as production and maintenance workers in an occupation with a fair amount of dust, then it would appear that the TLV for respiratory cancer expressed in terms of total mppcf-years might be somewhere between 100 and 200 mppcf-years.



IGURE. Total asbestos dust exposure and lung cancer mortality.

If the total dust estimate (mppcf-years) is separated into its two components, duration of exposure and average dust level, it is possible to test the assumption that time and dose should receive equal weight and are additive. This was done by constructing a 3 × 3 table with duration of exposure on one axis and average dust level on the other. For men in each of the nine cells in this table mean exposure years, mean exposure levels, and SMRs for respiratory cancer were calculated. From this it was possible to derive a linear multiple regression equation in which the SMR for respiratory cancer is the predicted or dependent variable. It is also possible to calculate correlation coefficients to see how well the combination of years worked and dust level predicts respiratory cancer excess, and how well each of these predicts respiratory cancer with the other held constant. These correlation coefficients are shown in Table 4.

TABLE 4

DEGREE OF RELATIONSHIP BETWEEN TIME, ASBESTOS DUST LEVEL, AND SMR FOR RESPIRATORY CANCER (ASSUMING A LINEAR MODEL)

Predicting variables	*Symbol*	*Correlation coefficient*	*Per cent variance explained (R^2 or r^2)*
Combination of time and level	$R_{1.23}$	0·850	0·722
Time at fixed level	$r_{12.3}$	0·738	0·545
Level at fixed time	$r_{13.2}$	0·772	0·596

Recalling that a correlation coefficient ranges from 0 for no predictability to 1 for perfect predictability, it is apparent, first, that a linear combination of duration and level of exposure is a good predictor of respiratory cancer excess and, second, that exposure time with dust level held constant predicts nearly as well as dust level with exposure time held constant. The meaning of exposure time in this context is uncertain. Whether the contribution of time to the incidence of respiratory cancer is primarily a reflection of increasing dose or a reflection of an increasing latent period would be difficult to establish, although it seems probable that both factors are involved.

An example of the use of the multiple regression equation is illustrated in Table 5. Here predicted respiratory cancer SMRs are shown for men working

TABLE 5

PREDICTED SMR FOR RESPIRATORY CANCER FOR MEN WORKING 25 YEARS AT SELECTED ASBESTOS DUST LEVELS (ASSUMING A LINEAR MODEL)

Dust level (mppcf)	*Predicted SMR (US expected)*	*Predicted SMR (US urban expected)*
5	195.3	171.3
10	257.8	226.2
15	320.4	281.0
20	383.0	335.9

25 years at various asbestos dust levels. SMRs are shown where the expected mortality is based on all US white males and where the expected is based only on white males living in urban areas.

Discussion

These data are similar to those reported by McDonald *et al.* (1971). In their study, both time and dust level appeared to make independent contributions to respiratory cancer increments. While direct comparisons of excess respiratory cancer are not possible, it is possible to compare the range of estimates in relation to the range of total dust exposure. In both studies, age-corrected respiratory cancer mortality rates at the highest level of total dust exposure are roughly three times those at the lowest.

The study presented here was relatively simple to conduct since all records needed, with the exception of death certificates, were available in industry. Estimates of dust levels for jobs as they existed during periods long past are obviously very crude and numbers were in many instances very small. Nevertheless the results appear to be coherent.

Had larger numbers been available it might hav been possible to identify more precisely a TLV f respiratory cancer in this type of population. Th available data suggest, however, that large incre ments in respiratory cancer appear at a cumulativ asbestos dust exposure of somewhere between 10 and 200 mppcf-years.

Abstract A case-control study, undertaken to identify reasons for the exceptionally high rate of lung cancer among male residents of coastal Georgia, revealed a significantly increased risk associated with employment in area shipyards during World War II. The summary relative-risk estimate, adjusted for smoking, other occupations, age, race and county of residence was 1.6 (95 per cent confidence limits = 1.1 to 2.3). A synergistic relation was found between shipyard employment and cigarette smoking. These findings suggest that asbestos and possibly other shipyard exposures during wartime employment account for part of the excess mortality from lung cancer in certain coastal areas of the United States. (N Engl J Med 299:620-624, 1978)

THE mapping of cancer mortality in the United States according to county, 1950-69, revealed an area along the southeast Atlantic coast where the rates for lung cancer were exceptionally high among white men.[1,2] To identify reasons for the elevated mortality, we conducted a case-control study of lung cancer diagnosed among residents of coastal Georgia.

Methods

Cases of primary lung cancer among male residents of an 11-county coastal area* were identified from three sources: diagnoses since 1970 at the single large hospital in Brunswick, diagnoses during 1975-76 at the three major hospitals in Savannah, and death certificates for the period 1970-74 among residents of Chatham (Savannah) and the neighboring rural coastal counties where death was attributed to lung cancer (eighth revision of *International Classification of Diseases* 162.1).

Controls were selected from admissions to the four hospitals and from death certificates for diagnoses other than lung cancer, bladder cancer or chronic lung disease. The hospital controls were nearest admissions at the same facilities of similar sex, race, age (±2 years), county of residence and current vital status. Two controls were chosen for each case in Brunswick (where the number of cases was smaller), and one for each case in Savannah. A single death-certificate control was selected for lung-cancer cases identified by death certificate according to similar matching criteria.

Personal interviews of the patients and controls, or their next of kin in the event that they had died, were conducted by locally hired public-health nurses and interviewers under the supervision of a professional survey organization. Each interviewer was trained in interviewing technics, including standardized methods of probing. Nearly all questions were in closed form to minimize inter-observer biases. Sample questions in 10 per cent of all interviews were later checked for verification by telephone.

Information was obtained on place, type and length of employment for all jobs held for six months or more. The respondents were asked to describe the duties performed for each job, as well as to list materials handled during the course of their work. The occupational section of each questionnaire was concluded by review with each respondent of a checklist of industries (including shipbuilding) and materials (including asbestos). Data obtained on cigarette-smoking characteristics for each respondent included, for those who had at some time smoked — "ever smokers" — the age they started, usual amount smoked, age (or ages) when they had stopped smoking and type of cigarette.

Estimates of the relative risk (odds ratios) of "ever" (six months or more) employment upon lung cancer were calculated for each of 16 industrial categories, including shipbuilding.[3] The relative risk estimates were determined for various strata categorized according to race (white or black), age at diagnosis or death (30-54, 55-64 and 65+), county of residence (Chatham, Glynn, and other), "usual" industry of employment (16 categories) and cigarette smoking (three categories). We calculated tests for interactions of the relative risks for shipbuilding across the various levels of the other factors, using a logistic representation of these retrospective data.[4] When effect modification was absent, summary relative risks were estimated and tested by this technic,[4] as well as by the Mantel-Haenszel method.[5]

To obtain an estimate of the possible effect of inaccuracies of next-of-kin responses, we conducted simultaneous interviews, usually of the husband and wife, for a small sample (24 pairs) of the study subjects and their next of kin.

Results

A total of 535 cases of primary lung cancer and 659 controls were identified from the Brunswick and Savannah hospitals and the Chatham and rural-county mortality series (Table 1). This distinction excludes 23 Savannah hospital cases in residents of smaller coastal counties, since appropriate hospital controls matched for county of residence for the group could not be easily obtained.

Interviews were completed for 89 per cent of the lung-cancer cases and 87 per cent of the controls. Of those not interviewed, about two thirds had moved out of the coastal area or could not be located; for the remainder, either the patient or next of kin (32 cases) or attending physician (14 cases) would not consent to interview. Approximately 4 per cent of the subjects interviewed had lived in coastal Georgia for less than five years and were excluded from the analysis. Thus, the study group consisted of 458 lung-cancer cases and 553 controls, most of whom were longtime residents (median of 41 years) of coastal Georgia.

The major findings of this study pertained to shipyard employment. Shipbuilding was the "usual" industry in eight cases (mostly workers in smaller shipyards) and one control (crude relative risk of 9.8). However, 95 patients and 80 controls (crude relative risk of 1.5) were employed at some time in the industry, most working for just a few years during World War II (only 21 per cent of the total worked in the in-

*Included were Brantley, Bryan, Camden, Charlton, Chatham, Glynn, Liberty, Long, McIntosh, Pierce and Wayne counties. The participating hospitals were Glynn-Brunswick Memorial Hospital, Candler General Hospital, St. Joseph's Hospital and Memorial Medical Center.

dustry for more than five years). As shown in Table 2, the risk ratios were greater than 1 regardless of the method of ascertainment for the series comprising this investigation.

The higher risk associated with shipbuilding was not accounted for by cigarette smoking. Table 3 shows elevated relative risks for shipbuilding in each of three cigarette-smoking categories. The first smoking category consisted of those who had never smoked, those who usually smoked less than half a package per day (whose risk relative to that of never smokers was 0.4) and workers who had stopped smoking at least 10 years before diagnosis (risk of 1.8), the second group included smokers who usually smoked half a package to 1½ packages per day (risk of 4.5), in addition to those (13 per cent of the total) whose usual amount smoked was unknown (risk of 6.2), and third, those who usually smoked two or more packages per day (risk of 8.6). The summary relative risk for shipbuilding, adjusted for cigarette smoking by the Mantel-Haenszel method, was 1.6 (P = 0.006).

Table 1. Numbers of Lung-Cancer Cases and Controls Identified for Study by Method of Ascertainment

Source of Identification	Period	Cases	Controls
Brunswick Hospital	1970-76	170	319
Savannah hospitals	1975-76	149	153
Death certificate	1970-74	216	187
Totals		535	659

The higher estimates of relative risk for shipbuilding were seen in both whites and blacks, in all age categories and in Glynn (Brunswick), Chatham (Savannah) and the rural coastal counties as well (Table 4). The higher risks for shipbuilding were also not readily explicable by other occupations. Table 5 shows that the distribution of the "usual" industries of employment of those who had worked in shipyards included a higher proportion of construction and farming jobs and a lower proportion in the paper and pulp industry than the distribution among those who had never worked in the shipbuilding industry. The relative risks for farming and the paper industry, adjusted for smoking, were 0.7 and 1.0, so that the differential representation in these two industries does not account for the increase associated with shipbuilding. There was a smoking-adjusted increased risk of 1.3 associated with construction, but the risk with shipbuilding was high among both construction and nonconstruction workers (Table 6).

When smoking, residence, age, race and usual industry were simultaneously taken into account in the logistic model, the adjusted summary relative risk was 1.6 (P = 0.01), with 95 per cent confidence limits of 1.1 to 2.3. Although the relative risks for shipbuilding increased with heavier consumption of tobacco, the differences in these risks among the three smoking categories were not statistically significant (P>0.10).

Table 2. Relative Risks for Shipbuilding According to Method of Ascertainment and County of Residence, Cases and Controls

Series	County of Residence	Case or Control	Ever Employed in Shipbuilding		Relative Risk
			yes	no	
Brunswick Hospital	Glynn	Case	19	62	1.7
		Control	23	130	
	Other rural	Case	10	45	1.3
		Control	18	101	
Savannah Hospital	Chatham	Case	23	111	1.4
		Control	17	116	
Mortality	Chatham	Case	32	91	2.0
		Control	14	79	
	Other rural	Case	11	54	1.2
		Control	8	47	

Nevertheless, the excess risk increased sharply with smoking (Fig. 1), indicative of a strong synergism between these two risk factors.

Table 7 shows relative-risk estimates according to types of shipyard jobs. An excess risk was not seen for welders or riggers, but was apparent for other groups, including those where direct exposure to asbestos would not be likely. Each interview requested information on whether asbestos was among the "materials handled at work." Among the 175 respondents in our study who had worked in shipbuilding, contact with asbestos was reported by only 10 (four cases and six controls).

Information obtained on the specific histologic types of primary lung cancer among the hospital series revealed no differences among those ever employed in the shipbuilding industry as compared to those never so employed.

The small sample evaluation of comparability of patient and next-of-kin responses revealed little difference in "usual" occupation according to type of respondent. The patients, however, tended to report a greater number of jobs ever-held (particularly in farming, although not in shipbuilding) than their next

Table 3. Relative Risks for Shipbuilding According to Cigarette-Smoking Category

	Control	42	220	
Heavy	Case	14	96	2.4
	Control	3	50	

*See text for definition of categories.

of kin. Concordance for smoking category was 83 per cent, with the discrepancies split between higher and lower consumption reported by the next of kin, in each instance with the classification by the study subject and next of kin being in adjacent categories. Most (76 per cent) of the interviews for the entire sample of 458 cases and 553 controls were with next of kin. When the total data were stratified according to type of respondent, the risk ratios for shipbuilding were 1.5 for self-respondents and 1.6 for the next-of-kin respondents.

DISCUSSION

Because of excellent community participation (less than 3 per cent of those approached refused interview), it was possible to cover nearly all the identified subjects in this case-control investigation. However, since lung cancer is often rapidly fatal — nationally the median survival is five months[9] — most of the interviews were conducted with the next of kin of deceased persons. Our sample check for comparability revealed generally good agreement between self and next-of-kin responses, but some inaccuracies may have resulted from second-party reporting, or from the difficulties in recalling events taking place 30 or more years before the interview. However, these possibilities seem unlikely to have produced any major differences between cases and controls.

A significantly higher risk of lung cancer was found in Georgia residents who worked in shipyards during World War II. The higher risk, which was observed in each of five independent series of lung-cancer cases and controls in this investigation, was not readily explicable by smoking habits or other occupational exposure. The excess was seen in white and black men in both Savannah and Brunswick, where two large shipyards began operations in 1942. By late 1943 about 22,000 were employed in the Savannah shipyard, and about 16,000 in Brunswick.[7,8] Both yards closed shortly after the war's end. Twenty-one per cent of the patients with lung cancer in our study reported working in the industry. Among the small number of men who continued to work in shipbuilding and repair at other locations, the risk of lung cancer was exceptionally high. It seems likely, therefore, that shipyard exposures account for at least part of the excess mortality from lung cancer in coastal Georgia. Assuming that 14 per cent (the proportion among controls) of the general population in the area had worked in the shipyards and were at 1.6 times the "usual" risk of lung cancer, and assuming that the remaining 86 per cent were at usual risk, the coastal lung-cancer rate would be expected to exceed the usual rate by about 8 per cent. Provisional estimates of mortality rates from lung cancer for 1970-75 among white men show that the rates in the area

	Control	11	38		

exceed the national rate by about 30 per cent, suggesting that the coastal excess may be only partly attributable to wartime shipyard exposures. However, it is possible that the maximum effect of exposures during World War II occurred before the 1970-76 period of investigation, so that the risks presented in this study may be underestimates.

Ship construction and repair involves contact with asbestos,[9,10] which is known to induce lung cancer and mesothelioma, but few data on this exposure are available from our survey. Only 5 per cent of those ever employed in the shipyards reported handling asbestos during shipyard duties, with only one classified as an insulator. The lung-cancer risk did not seem limited to any particular shipyard trade, in agreement with reports from Europe of mesothelioma among various classes of shipyard workers.[10-16] Asbestos-related lung disease has been seen in pipecoverers in shipyards in the United States[17] and also among other workers regardless of their occupation within the industry.[18] Furthermore, the multiplicative effect between shipyard employment and cigarette smoking in our study is consistent with other reports of a synergism between exposure to asbestos and smoking on lung-cancer risk.[19]

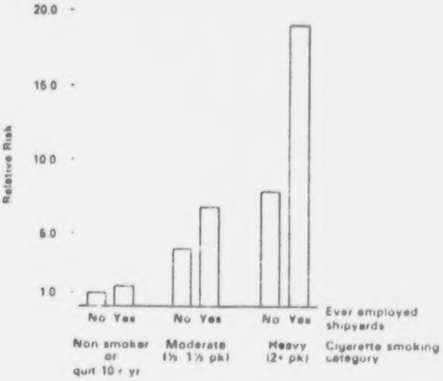

Figure 1. Relative Risk of Lung Cancer According to Usual Cigarette Smoking Category and Employment in Shipyards during World War II.

Despite the increased mortality from lung cancer in coastal Georgia, we found only five cases with mesothelioma and two with asbestosis through a search of medical records and pathology files since 1960 in the participating hospitals. This number of cases of mesothelioma was not higher than the national incidence estimated at about two cases per million per year,[20] but diagnostic ascertainment in the area may be incomplete. On the other hand, since mesotheliomas have been reported to occur even after relatively light exposures to asbestos,[21,22] the failure to see greater numbers of this rare tumor among coastal residents raises the possibility of shipyard hazards in addition to asbestos.

Table 7. Relative Risks for Ever Employment in Major Shipbuilding Job Subcategories

SUBCATEGORY	CASES*	CONTROLS*	CRUDE RELATIVE RISK
Insulator, boiler maker	2	2	1.2
Pipefitter	10	4	3.1
Shipfitter, steamfitter	6	5	1.5
Welder, burner	11	20	0.7
Rigger, leaderman	6	9	0.8
Machinist, machine operator, metal worker	13	11	1.4
Laborer, construction	24	20	1.5
Electrician	5	3	2.0
Clerk, accountant, draftsman, guard	7	3	2.8
Not specified	15	5	3.7

*Total no. slightly exceeds no. ever employed in the shipbuilding industry since persons with jobs in ≥2 categories were counted in each.

Further studies of shipyard workers should help quantify the risk of lung cancer, mesothelioma and other tumors seen after exposure to asbestos.[23] The magnitude of the problem may be greater than has previously been thought, since counties throughout the United States with wartime shipyards tend to have elevated mortality not only from lung cancer but also from cancers of the larynx, oropharynx and upper gastrointestinal tract.[24]

EFFICACY OF CHEST PHYSIOTHERAPY AND INTERMITTENT POSITIVE-PRESSURE BREATHING IN THE RESOLUTION OF PNEUMONIA

William G. B. Graham, M.D., and Deborah A. Bradley, B.S.

With the assistance of Rhonda Kleczek, B.S., R.P.T., and Diantha Bartlett, M.S., M.A., B.A.

Abstract We undertook a randomized clinical trial to evaluate the efficacy of chest physiotherapy and intermittent positive-pressure breathing in the treatment of pneumonia. The diagnosis of pneumonia required a compatible clinical history and x-ray confirmation. A total of 54 patients were assigned to treatment and control groups and were similar in age, smoking history, underlying lung disease and prior antibiotic treatment. Antibiotic therapy, guided by Gram stain and sputum and blood cultures, was similar in both groups. Chest physiotherapy, consisting of postural drainage, percussion and vibration, was given concurrently with intermittent positive-pressure breathing with use of racemic epinephrine every four hours. There was no statistically significant difference in duration of fever, extent of radiographic clearing, duration of hospital stay and mortality between the control and treated groups. Chest physiotherapy and intermittent positive-pressure breathing do not hasten the resolution of pneumonia. (N Engl J Med 299:624-627, 1978)

A RECENT symposium[1] held under the auspices of the American Thoracic Society evaluated the scientific basis of respiratory therapy, including chest physiotherapy and intermittent positive-pressure breathing. These therapies, now extensively used in diverse bronchopulmonary disorders, have not often been validated by randomized clinical studies, or such studies have failed to show clinical benefit.[2-5] One application not previously studied is their efficacy in the treatment of pneumonia. Despite the lack of data concerning effectiveness in this common clinical situation, an in-house retrospective study of 100 consecutive patients hospitalized at the Medical Center Hospital of Vermont with pneumonia revealed that chest physiotherapy and intermittent positive-pressure breathing were used as therapeutic adjuncts in two thirds of the cases. Furthermore, a survey carried out on the treatment of pneumonia in four regional hospitals in Vermont showed that as many as 64 per cent of patients received intermittent positive-pressure breathing, and 44 per cent received chest physiotherapy — a frequency of use estimated to occur nationwide (Baker JP: personal communication). To assess the effects of this form of therapy in hastening the resolution of pneumonia, we conducted a randomized prospective clinical trial.

Methods

Patients admitted to a pulmonary unit with a radiographic diagnosis of pneumonia and a compatible clinical history of fever and increased cough were eligible for randomization. Informed consent was required. Patients were excluded from the study by any of the following complicating factors: lung abscess, established underlying bronchiectasis, tuberculous pneumonia or cystic fibrosis, respiratory failure (partial pressure of carbon dioxide over 50 mm Hg) or a need for assisted ventilation, presence of renal failure (blood urea nitrogen over 40 mg per deciliter), immunosuppressive therapy (receiving more than 40 mg per day or equivalent of prednisone, azathioprine or antineoplastic agents), stroke within six weeks, and underlying cancers.

Patients with other underlying cardiopulmonary disorders such as heart disease or chronic obstructive lung disease were included, as were those with medical conditions such as alcoholism and diabetes. Postoperative patients were not studied.

The randomization procedure pre-stratified patients on the basis of age (under or over 55 years), smoking history (smoker vs. nonsmoker), sex and prior antibiotic therapy. The house officer looking after the patient then selected a pre-randomized sealed envelope containing a control or treatment group label, which assigned the patient.

Dust exposure and mortality in chrysotile mining, 1910-75

J C McDONALD,[1] F D K LIDDELL,[2] G W GIBBS,[2] G E EYSSEN,[2] AND A D McDONALD[3]

From the TUC Centenary Institute of Occupational Health, London School of Hygiene and Tropical Medicine, London, UK,[1] the Department of Epidemiology and Health, McGill University, Montreal, Canada,[2] and the Department of Epidemiology, St Mary's Hospital Medical School, London, UK[3]

ABSTRACT We report a further follow-up of a birth cohort of 11 379 workers exposed to chrysotile. The cohort consisted of all 10 939 men and 440 women, born 1891-1920, who had worked for at least a month in the mines and mills of Asbestos and Thetford Mines in Quebec. For all subjects, length of service and estimates of accumulated dust exposure were obtained, with a smoking history for the vast majority. Three methods of analysis, two based on the "man-years" method, the other a "case-and multiple-controls" approach, gave results consistent with one another and with previous analyses.

By the end of 1975, 4463 men and 84 women had died. Among men, the overall excess mortality, 1926-75, was 2% at Asbestos and 10% at Thetford Mines, much the dustier region. The women, mostly employed at Asbestos, had a standardised mortality ratio (SMR) (all causes, 1936-75) of 0·90. Analysis of deaths 20 years or more after first employment showed that in men with short service (less than five years) there was no discernible correlation with dust exposure. Among men employed at least 20 years, there were clear excesses in those exposed to the heaviest dust concentrations. Reanalysis in terms of exposure to age 45 showed definite and consistent trends for SMRs for total mortality, for lung cancer, and for pneumoconiosis to be higher the heavier the exposure. The response to increasing dose was effectively linear for lung cancer and for pneumoconiosis. Lung cancer deaths occurred in non-smokers, and showed a greater increase of incidence with increasing exposure than did lung cancer in smokers, but there was insufficient evidence to distinguish between multiplicative and additive risk models. There were no excess deaths from laryngeal cancer, but a clear association with smoking. Ten men and one woman died from pleural mesothelioma.

If the only subjects studied had been the 1904 men with at least 20 years' employment in the lower dust concentrations, averaging 6·6 million particles per cubic foot (or about 20 fibres/cc), excess mortality would not have been considered statistically significant, except for pneumoconiosis. The inability of such a large epidemiological survey to detect increased risk at what, today, are considered unacceptable dust concentrations, and the consequent importance of exposure response models are therefore emphasised.

Mining, milling, and processing of the asbestos group of fibrous minerals, long known for their remarkable strength and fire resistance, began on a commercial scale at the end of the nineteenth century. In the Eastern Townships region of Quebec deposits of chrysotile were noted in the 1847 Canadian Geological Survey. Exploitation began at Thetford in 1878 and four years later some 60 miles away near Danville. Within 30 years the region was producing most of the world's asbestos. The proportion fell as Russian, South African, and Italian mines came into operation, but Quebec still produces about 25% of the world's supply, now estimated at about six million tons a year; indeed, production in Quebec and elsewhere has continued to expand.

In and around Thetford many companies started mining, and the town was renamed Thetford Mines.

Received 12 January 1979
Accepted 11 April 1979

Amalgamations and closures over the years reduced the number of companies to six. One large company has operated near Danville, and the new town of Asbestos was built; this company has also manufactured asbestos products in a small local factory. There was formerly a small mine a few miles away, owned by another company, which is included with the companies of the Thetford area for the purposes of this paper.

Attention drawn at the New York Academy of Sciences in 1964 to the serious threats to health posed by airborne asbestos dust led immediately to recommendations[1] that epidemiological inquiries were urgently needed in populations exposed to single types of fibres. At the invitation of the Canadian Government, and with encouragement from the Government of Quebec, a research programme was established in 1966 at McGill University to study the health effects of work in the Quebec chrysotile-producing industry. Results of the first three years' work, which included the reading of 16 000 chest radiographs, comprehensive tests on a sample of current workers, and studies of mortality to the end of 1966 were summarised by McDonald *et al* in 1974.[2]

Our knowledge of the mortality experienced by chrysotile workers is derived from observations on a birth cohort (1891-1920) of 10 939 men and 440 women followed from first employment (the earliest in 1904) to the end of 1975, by which time 4463 men and 84 women were known to have died. The first death was due to an accident in 1910, and another 112 men died before the end of 1925, mainly through accidents or respiratory tuberculosis. During the five decades, 1926-75, 4350 men died compared with 4107 expected on the basis of Quebec age- and year-specific death rates, a standardised mortality ratio (SMR) of 1·06, but the evolution of mortality in the cohort differed substantially in the two mining areas.[3] Table 1 shows that there were almost equal numbers of employees in the two mining areas, Asbestos and Thetford Mines. The numbers in each of the six quinquennia of birth were similar, varying only between 1509 and 1969. The first excesses which were during the war years, were about equal in the two areas, and may have been attributable, at least in part, to the exclusion, until 1944, from the Quebec vital statistics of deaths in military personnel outside Canada. In the decade 1946-55 there were 42 fewer deaths than expected at Asbestos but 16 more than expected at Thetford Mines. From 1956 to 1970 there were excesses in both areas, but considerably less at Asbestos (78) than at Thetford Mines (173). In the final period, 1971-5, there were 18 fewer deaths than expected at Asbestos, but still an excess of 12 at Thetford Mines. During the five decades, 1926-75, there had been a net excess of 33·9 deaths at Asbestos (1·6% of the 2074·1 expected) and of 208·8 at Thetford Mines (10·3% of 2033·2) – that is, SMRs of 1·02 and 1·10 respectively.

The primary aim of the mortality survey was "to define as accurately as possible the quantitative relationship between exposure to chrysotile asbestos and the incidence of lung cancer."[4] The present paper reports the results of the follow-up until the end of 1975. Mortality from lung cancer is associated with smoking, and the concern must be to attempt to separate the hazards. It is also important to consider total mortality, if only to confirm that an excess of deaths from lung cancer does not blind us to a shortfall of greater magnitude from other causes, as has sometimes occurred in other surveys. Additional aims were to measure exposure-response relations for other malignant diseases, particularly cancers of the gastrointestinal tract and larynx, and for pneumoconiosis and other respiratory diseases.

Material and methods

In November 1966 a register was compiled of everyone, nearly 30 000, ever employed in the Quebec chrysotile production industry. A small proportion, who worked at the factory in Asbestos, were also included because of the movement of employees between it and the mine or mills. Everyone born between 1891 and 1920 inclusive and employed for one month or more was identified from the register. These criteria for admission to the cohort were chosen to ensure a wide range in levels of exposure and durations of employment, while those born before 1891 would have been particularly difficult to trace and those born after 1920 have yet to reach the age of high mortality. All available means were adopted in attempts to trace every person in the cohort[3]; there was no appropriate social security system to facilitate this. For all deaths, exact dates and places were sought so that copies of death certificates could be obtained. The cause of death was coded according to the International Classification of Diseases (7th revision) by a person who regularly performed this task for the Quebec Department of Vital Statistics.

Tracing has been carried out to four points in time: 31 October 1966,[3] to the end of 1969,[2,5] to the end of 1973,[6] and now to the end of 1975. The proportion traced has slightly improved over the years; most of the 9·9% still lost to view were men with short service many years ago; less than 2% were untraced after 1935. The total cohort now numbers 11 379 (10 939 men and 440 women) whereas it was originally estimated[1] as 11 788. The reduction has been due to improving information which permitted (a) more stringent application of admission criteria and (b) better recognition of cases in which the same employee had been separately registered with different companies or under different names. In the nine years since our first report the number of deaths has increased from 2457 to 4547, now comprising 44·3% of those traced. By the end of 1975 the youngest people alive in the cohort were 55 years old, the oldest 84.

Much work was put into determining the dust exposure for each subject, as described by Gibbs and Lachance.[7] In essence, some 5783 jobs were identified from detailed work histories, and for each one, for each applicable year, an average dust concentration was estimated in millions of particles per cubic foot (mpcf) from available dust measurements and approximations. Estimates were based on well over 4000 midget impinger dust counts measured, between 1949 and 1966, by Maurice Lachance, ingenieur, in annual surveys in all companies. Before 1949 there had been few measurements, so estimates were made by Gibbs and Lachance after interviews with long-service employees and comparisons with more recent conditions.

For each person in the cohort, we defined his or her

Gross service—The period from start of first job to termination of last job (or to November 1966, if earlier).

Net service—The total of periods of actual employment.

Service gap—(Gross service less net service)/(gross service), as per cent.

Accumulated dust exposure—The total of annual dust exposures, summed over defined periods; the units are mpcf multiplied by years (mpcf y).

Smoking habit was assessed by a questionnaire, answered by 99·6% of those alive in 1970 and by the relatives or friends of 93% of those who died after 1950; for earlier deaths, numbering 816, it was thought that smoking histories would often not be obtainable or sufficiently reliable. Each man has been classified according to his reported smoking habit at the time of report as non-smoker, moderate smoker, or heavy smoker—that is, one who smoked 26-50 cigarettes a day.

The data to 1966 and those to 1969 were analysed primarily by a method which was recognised[4] as having two weaknesses: (1) that deaths accumulated over many years were used without regard for age at death, and (2) that length of exposure was related to length of survival. These problems were covered in part by subsidiary analyses included in our first two reports[1,3] and in a more satisfactory but preliminary way in a third more comprehensive paper.[2] Although it was appreciated that an analysis based on man-years of exposure with comparison against an external reference population[8] was the orthodox approach to the problem, this too had its weaknesses. After a period of exploration and consultation,[9] the 1973 mortality data were used for an appraisal of methods of cohort analysis and presented for discussion at a general meeting of the Royal Statistical Society.[9] The merits and practical usefulness of the man-years method (which reasons a priori—that is, from cause to effect) were confirmed, but, clearly, an approach using a small fixed number of controls for each death,[10] and arguing a posteriori (from effect to cause), had other advantages. In particular it is efficient for examining interaction between several stimulus variables—for example, smoking, dust concentration, and duration of employment—and it does not depend on the availability of death rates for a reference population. Although rates for Quebec have been available since 1926, the appropriateness of this or any other reference population has always to be questioned. In this latest report we have used both methods; in addition we have made use of certain findings from the detailed analyses of deaths to the end of 1973 by Liddell *et al.*[11]

A PRIORI ANALYSES

For the man-years method, and to avoid possibly misleading non-standard terminology, we have continued to use the following definitions.

Subcohort—A division of the cohort, according to some factor(s) such as years of exposure or smoking habit.

Study interval—The interval over which each subject is studied in a particular facet of the study—which is not necessarily the same as the period over which the subject has been in view.

There are several aims, mainly conflicting, in the definition of subcohorts: they should be mutually exclusive and comprehensive, fairly equal in size, and large enough to provide reliable measures of mortality yet small enough to be homogeneous, preferably with at last three classes of each factor of interest in the relations of dose to response. There are usually several such factors, however, and their interactions may be important, so that many subcohorts are necessary. The compromises adopted are described below.

For a first series of analyses, the male cohort was subdivided initially by length of gross service, the boundaries being taken at one year, five years, and 20 years; thereafter, each gross service group was divided into four more-or-less equal classes according to accumulated dust exposure. For those with very short service (less than one year), the three margins between the dust groups were drawn at 1, 3, and 10 mpcf y; for those with short service (one to five years), the margins were at 6, 30, and 100 mpcf y; and for medium service (five to 20 years), at 30, 100, and 300 mpcf y. For the long-service group (at least 20 years), the classification, with boundaries at 100, 300, and 600 mpcf y, was made in terms of dust exposure accumulated in the first 20 years from start of service. The study interval for this first series of analyses started, in all four service groups, at 20 years after first employment in the industry, thus excluding only 21 deaths due to asbestos-related disease that had occurred within the first 20 years.

Relative risks of lung cancer were considered in detail by Liddell *et al*,[6] and it appeared that there was little to suggest that the way in which dust exposure had been accumulated played any part in determining the risk. It therefore seemed appropriate to base a second series of analyses on dust exposure accumulated to a certain age, arbitrarily taken as 45 years, at which age most men had completed their service. After the cohort had been divided by exposure to age 45, two further, but separate, subdivisions were made by mining area (Asbestos and Thetford Mines) and by smoking habit; those whose smoking habit was unknown being added to the largest group—that is, moderate smokers. The study interval started at age 45.

From data for Quebec obtained from Statistics Canada, we assembled mid-year populations and deaths from all causes in five-year age-groups (15-84) for men for the years 1926 through 1974, and for women for the years from 1936, the earliest practicable year, to 1974; the material for the last year was duplicated to provide estimates for 1975. Statistics Canada also provided magnetic tapes containing age, sex, and cause of all Quebec deaths, 1951-73, coded to the International Classification of Diseases for the 12 specific groups of causes defined in table 2. The numbers of deaths for "other known causes" were obtained by subtraction. Annual death rates for the reference population were calculated for five-year age-groups, 15-84, from the mid-year populations, 1951-75; those for 1973 were replicated twice to give estimates for 1974 and 1975.

A POSTERIORI ANALYSIS

The Miettinen method[10] uses a fixed number of controls for each case of interest. Our selection of internal controls was strictly at random from among those miners known to have survived to a greater age than that at which the case died and to have been born in (or as close as possible to) the same year as the case. Each control came from the same mining area as the case; for some purposes, one control was matched for smoking habit with the case. Those of unknown or doubtful habit were classified as "undifferentiated" and three groups of definite smokers were considered in the matching—that is, those smoking 15-25, 26-35, and 36-50 cigarettes a day. An attempt was made to match precisely into the subgroups, but for definite smokers relaxation was not infrequently necessary, and indeed in a few cases the control had to be found from the "undifferentiated" class.

The causes of death studied in this way, with the numbers of controls selected with and without regard for smoking were as follows: pneumoconiosis (1, 3); lung cancer (1, 3); abdominal cancers (0, 2); laryngeal cancers (1, 3); and mesothelioma (1, 4). For these analyses, the dust exposure was calculated up to nine years before the death of each case and to the same age for his controls.

Results

MEN

Just under half the men from each area were known to be alive in 1976, but one-tenth had been lost to view (table 1). Most of these losses were before 1936; in a review of the situation when tracing had been completed to the end of 1973 it was found that of 9723 men known to have been alive in 1936, 5797 had been traced alive, 3750 were known to have died, and only 176 were untraced (59.6%, 38.6%, and 1.8%, respectively).

Table 1 *Constitution of male cohort at end of 1975 (Percentages in parentheses)*

	Asbestos	*Thetford Mines*	*Composite cohort*
Alive	2608 (49.2)	2779 (49.3)	5387 (49.2)
Dead	2179 (41.1)	2284 (40.5)	4463 (40.8)
Lost to view	515 (9.7)	574 (10.2)	1089 (10.0)
Total	5302 (100)	5637 (100)	10939 (100)

The 4463 male deaths are shown in table 2 by year, age, and certified cause. Deaths from pneumoconiosis and lung cancer were generally at ages over 45 and from 1956 onwards. Respiratory tuberculosis was a major cause of death until the early 1950s, while accidents (including, but not dominated by, accidents at work) have been a common cause of death throughout, particularly in those under 45. In a total of 125 deaths (2.8% of all deaths), cause could not be ascertained, partly because death registration was not universal in Quebec until 1926, and partly because some death certificates were not found.

The number of death certificates on which it was stated that a necropsy had been carried out was 789

*Code in the 7th revision of the International Classification of Diseases

(17·7% of all deaths), and necropsy reports were obtained for the majority. These showed nine extra cases of lung cancer, but to maintain comparability with the general population only the coded causes of death were used throughout. Ten male deaths due to pleural mesothelioma were identified, nine from death certificates and one at necropsy. Six of these had been coded to lung cancer (ICD 162 or 163).

Table 3 describes the cohort by duration of employment; generally shorter at Asbestos than at Thetford Mines. In table 4 the four service groups have been further subdivided, as described in the

Table 3 *Gross service of men, by mining area. (Percentages in parentheses)*

*Found as average of dust exposure accumulated over gross service divided by average net service and expressed as million particles per cubic foot (mpcf)

previous section. In making these subdivisions priority was given to keeping subcohorts of adequate size for analysis, rather than to maintaining the same boundaries between dust concentration categories. Table 4 shows, nevertheless, that the mean *concentrations* (mpcf) in each set of four did not range very widely: low: 2.5 to 4.2; medium: 4.3 to 9.4; high: 14.4 to 23.6; very high: 46.8 to 82.6.

Dust concentrations have always been lower at Asbestos than at Thetford Mines. Thus to qualify for high dust exposure men at Asbestos had to have started work earlier or to have had longer service, particularly net service; gaps (as recorded) also were shorter, proportionately, at Asbestos. For the second form of a priori analysis, the men were classified by their dust exposure accumulated to age 45 (table 5). There is recent evidence that a very few employment gaps, some due to war service, did not appear in the work histories at Asbestos, and so exposures may be slightly overstated there. Nevertheless, table 5 shows a substantially lower proportion of men at Asbestos with exposures greater than 300 mpcf y.

Total	5302 (100)	5637 (100)	10939 (100)

Despite some difficulties in the classification of smoking histories (mainly because these had not been obtained for most of those lost to view nor for about 800 men who had died before 1950; but also because of certain coding errors[6] (which we did not consider important enough to correct) there appear to have been only small differences between the two mining areas, and no major association between smoking habit and dust exposure to age 45. There were, however, clear differences in the reported smoking habits of the men born in the six quinquennia: the proportion of non-smokers was 24.9% among those born 1891-5 and lower in each succeeding quinquennium, being only 9.3% among those born 1916-20; correspondingly, the proportions of heavy smokers rose in each quinquennium, from 2.9% to 12.3%.

Tables 6 and 7 analyse the 3291 deaths, 20 or more years after first employment, occurring from 1951 to 75. Comparison with table 2 shows that, although 26.3% of all observed deaths were thus excluded from the analysis because they occurred before 1951 or within 20 years of first employment, over 90% of deaths from pneumoconiosis and from lung cancer were included, and percentages were also high for malignant neoplasms of other sites (except the larynx) and stroke. Only small proportions, however, were included of deaths from respiratory tuberculosis (23.0%) and from accidents (39.7%), with other specific groups of causes intermediate.

When account is taken only of length of service (table 6), trends of risk, as measured by the ratios of observed to expected deaths—that is, SMRs in which the standardisation was by both age and era—

Columns headed O give the numbers of deaths of men 20 years or more after first employment, occurring during 1951-75; figures under headings SMR are ratios of deaths observed to those expected on basis of male mortality in Quebec.

were generally without clear trends, probably reflecting differences in selection and other factors already discussed. Exceptions were deaths attributed to pneumoconiosis and to accidents: of the 42 deaths from pneumoconiosis 36 were in men with at least 20 years' service; the trend with accidents was in the reverse direction, but it must be emphasised that, as the study interval started only 20 years after first employment, the trend is not a reflection of early work accidents in the asbestos industry shortening service prematurely.

Among those in the very short and short service groups—that is, those with gross service of less than five years (tables 7(a) and (b))—careful study of differences between groups according to severity of exposure showed no consistent pattern. Table 7(c) deals with men with gross service between five and 20 years; their service had also been completed before the start of the study interval. There were fairly consistent trends for higher SMRs the greater the dust exposure for total mortality, for pneumoconiosis (although based on only two deaths), heart disease, and stroke. In addition SMRs were highest in the group with the most severe exposure, for lung cancer and "other" respiratory diseases. All these findings are understandable as pulmonary fibrosis could well contribute directly to cardiopulmonary disease and, in addition, might adversely affect the probability of survival in any life-threatening condition. Table 7(d) concerns 3105 men

Table 7 *Deaths, by cause, in relation to dust concentration*

with at least 20 years' service, and an average of almost 32 years of employment (table 4). Here, the most severely exposed had the highest SMR not only for total mortality but for all listed causes other than laryngeal cancer and accidents. Further, the tendency for increased risk with each augmentation in exposure was completely consistent for pneumoconiosis and for heart disease, and positive, although rather less consistent, for total mortality, lung cancer, respiratory tuberculosis, and other respiratory diseases.

The other form of a priori analysis, with exposure calculated to age 45 at which age the study interval started, is summarised in table 8. The total number of deaths observed in this analysis was 3448 (77.3% of all deaths), with SMR = 1.07, very close to that for all causes in the complete cohort as given in table 6. Indeed, for each cause of death, SMRs from both methods of analysis were always close.

Clear trends were found for SMRs to be higher the heavier the exposure, for total mortality, pneumoconiosis, lung cancer, cancer of colon and rectum, respiratory tuberculosis, other respiratory diseases, and stroke. The trends were most clear-cut in pneumoconiosis and lung cancer, appearing in both Asbestos and Thetford Mines. The lung cancer trend was essentially linear as shown in the figure, where exposures of 30 mpcf y or more have been broken down further, into four classes. The trend for respiratory tuberculosis was also consistent in the two areas, but not those for the other causes listed here. The risk of death from cancer of the oesophagus or stomach was highest in the most severely exposed, but only at Thetford Mines; so was the risk of death due to heart disease, but only at Asbestos. Other abdominal cancers and laryngeal cancers were

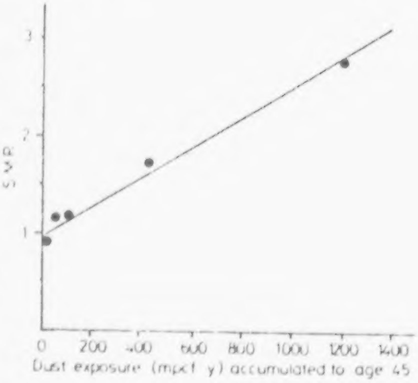
*See text for definitions



Lung cancer SMRs in relation to dust exposure accumulated to age 45. The line has been fitted by a modified least squares technique inversely related to exposure, and no other patterns could be elucidated.

The last line of table 9 is repeated from the previous table, but the right-hand margin shows a clear and substantial effect of cigarette smoking. For each category of smoker, the risk of lung cancer was lowest among those with low exposure to age 45 and highest among those with exposure of at least 300 mpcf y by that age. The interaction between the factors of smoking and dust exposure is examined later (table 11).

Corresponding detail for laryngeal cancer is confusing because of the very small number of deaths from this cause. As already seen (table 8), the dust effect was, if anything, inverse; however, the smoking effect was quite strong: non-smokers, two deaths, SMR = 0.46; moderate smokers, 10 deaths, SMR = 0.93; heavy smokers, five deaths, SMR = 4.85.

Table 10 summarises the findings from the Miettinen approach, that is, more than one control for each case, excluding those for smoking habit; the numbers of deaths are as in table 2 (but see footnote ‡ in table 10) because there were no restrictions on the start of the study interval. Four groups of dust exposure are distinguished, and the data are presented without regard to the matching. Matching was taken into account in the full analysis, however, which generally confirmed the tendencies shown in the two a priori approaches (Thomas, DC, unpublished), and relative risks were fairly similar at Asbestos and Thetford Mines.

‡Excluding five deaths coded to 162-164 but found to be due to malignant mesothelioma.

The interaction between dust exposure and smoking in lung cancer mortality is explored in table 11, where the distribution of dust exposure of the single control matched so far as possible for smoking is compared with that of the cases in each smoking category separately. The final section of this table differs from the corresponding part of the previous table because of the different selection of controls, but the relative risks are similar. Further, the relative risks within smoking categories are in reasonable accord with those obtainable from table 9, despite major differences in the methods of determining them.

Clearly lung cancer can occur in non-smokers, and indeed it might seem from our data that the relative risk due to asbestos dust exposure was, in fact, higher for non-smokers than for smokers. Linear dose-response relations have been fitted (Berry, G, unpublished), so far without regard for smoking: using the data on which table 10 is based, but taking into account the matching of controls for each case in terms of date of birth and place of employment, the fitted line was

$$\text{Relative risk} = 1 + 0{\cdot}0014\ (\text{mpcf y})$$

the standard error of the estimate of the slope being 0·0005. The linear fit accounted for χ^2, with one degree of freedom, of 21·37, leaving only a very low value for deviations from linearity.

There were in all 11 deaths (including one of a woman) from malignant mesothelial tumours observed to the end of 1975. All were of the pleura and appeared to follow a clear exposure trend. The problems of interpretation are complex, however, and the subject will be examined in detail elsewhere.[11]

WOMEN

Of the 440 women in the cohort, only 31 were lost to view (7·0%), a better rate of tracing than for men. Of those traced, 325 were alive until 1976 (79·5%) and 84 had died (20·5%), the lower percentage mortality than in the men being largely explained by the younger age of the women. The women had been employed mainly at Asbestos (408 (92·7%)), and only 84 (19·1%) had been exposed to more than 30 mpcf y by age 45. In addition to the case of pleural mesothelioma mentioned above, there was one death from lung cancer, compared with 1·19 expected. Careful study of the remaining detail showed no other exposure-related effect.

Discussion

This survey, begun in 1966 and continued without interruption for 12 years, has sought to determine the quantitative relations between occupational exposure in the chrysotile production industry of Quebec and mortality. Since analyses conducted at four stages during the 10-year period, by increasingly varied and sophisticated statistical methods, have been closely consistent,[3] we conclude that our objective has been achieved. Essentially linear relations have been shown between indices of exposure, based on dust concentration (mpcf) multiplied by length of service, and lung cancer, pneumoconiosis, and total number of deaths. Using this measure of environmental quality, we are now able to assess, with reasonable confidence, the mortality risk associated with work at different levels of dust concentration and for social decisions to be made as to what level, if any, is "acceptable."[12] As almost half of the cohort is now dead, no further study would appear necessary were it not for the current trend toward setting hygiene standards in terms of fibre rather than dust counts — despite the almost complete lack of epidemiological data based on fibre measurements. There would be no serious problem were the conversion a simple one. The evidence of Gibbs and Lachance[13] shows that this is not the case and so we have now embarked on a laborious attempt to estimate past exposures in fibres/ml and will use these in further analyses of our mortality and morbidity findings. In the meantime we may note the results of an analysis of Gibbs's data by Dagbert,[14] which showed that, at the relevant dust levels, the conversion factors range from about 3 to 7 fibres/ml for each mpcf. Further data now available to us, however, point to a lower range, perhaps 1 to 5.

When considering what degree of environmental exposure can be regarded as "safe," a linear response to exposure is a great convenience.[3,15] It allows extrapolation to exposure levels far below those at which reliable direct measurement of risk is possible. Our findings by two methods of analysis conform well with the hypotheses of linearity, but they do not constitute proof. It is not unreasonable, however, to suppose that the probability of initiation of the malignant process by mutation may be dose-related and that defence mechanisms will not change this.

Similar uncertainty remains over the form of interaction between asbestos exposure and cigarette smoking. Our data seem as compatible with the "additive model" of relative risk (model 1) discussed by Saracci,[16] as with the "multiplicative model" — that is, with the simplest form of his model 2; they are quite incompatible with model 3, in which "asbestos can only increase lung cancer in the presence of smoking." Either model allows one to speculate that the dust concentrations in the Quebec mills in the early 1950s, before effective dust suppression was introduced, carried a lung cancer risk equivalent to heavy smoking whereas, at more recent concentrations of around 1 mpcf, the order of risk may now approximate to less than one cigarette a day. Despite the much greater sophistication of the "matched" case-control analyses of the data (Thomas, DC, unpublished), they gave essentially the same results as our "unmatched" analysis, and so far have not been able to increase confidence in the exact form of the interaction.

Several factors bearing on the validity of this survey warrant examination. A study of this kind is as good as the environmental and mortality records on which it is based. On the former we can add little: the very large number of environmental measurements made in this industry since about 1950 have been used to the full, but for the more important earlier years we have only our estimates to go on.

While this is frankly acknowledged, two points can be made: (1) the estimates were based on many years of extensive study of Quebec mines and mills with very varied hygiene standards; and (2) random errors in exposure estimates would have been expected to obscure rather than enhance correlation between exposure and response.

At least equal effort was put into the follow-up and ascertainment of registered causes of death. In terms of completeness we believe this satisfactory; almost all of the 10% of subjects lost to view were men with short service many years ago; over 98% were traced after 1935 and a cause was obtained for 97% of deaths.

Questions remain, however, on the validity of recorded cause of death and on possibilities of related bias. These questions apply only to cause of death and not to the fact of death—the more important issue. It must be faced that, in this, as in other occupational cohort studies, there is considerable scope for diagnostic bias. In writing a death certificate most physicians prefer probable to improbable causes; men who die of respiratory disease after long heavy exposure to dust could well have had pneumoconiosis, whereas this must be considered unlikely in men without such history. Selective necropsies will, if anything, increase this type of bias. Even a 100% necropsy rate in the study population would overcome the problem only if the same population is used as the basis for calculating expectations. The net result, discussed in our first report on this cohort,[4] is that there may be a bias towards the over diagnosis of dust-related disease in men with heavy exposure. The effect will be intensified by a greater frequency of necropsies in deaths where a prima facie case for compensation exists. There was evidence of this in the high necropsy rate (52%) in deaths ascribed to pneumoconiosis. The effect of this trend might well overflow into those causes of death—especially cancer of the lung and other organs—which are under-diagnosed without necropsy. None of this, however, affects the validity of the exposure-response relation for deaths (all causes), although conceivably it contributes to the linearity and excess for pneumoconiosis and lung cancer.

A related problem in cohort studies is the so-called "healthy worker effect" (see, for example, Fox and Collier[17]) resulting from non-random selective entry and exit from various industries and for jobs within the industries. It is an unfortunate term because these selective forces, dependent on circumstances, may result in healthy or unhealthy worker effects. These effects matter because no observational study in epidemiology can correct for them; this is especially so in a priori analyses of the man-years type using an external reference population. Tables 6, 7(a), and 7(b) show some of the problems of interpretation: men with gross service less than five years (*a*) had about the same SMRs for all causes (1·07, 1·09) as those with long service (1·07); and (*b*) had SMRs that were higher at the lower exposure levels. Part of the explanation may be that the less fit went to the less heavy or less dusty jobs and often did not stay long in the industry. Another part may be that those with the shortest employment were the most difficult to trace, and among them death was probably more completely ascertained than survival, but this effect must be small because of the high trace rate actually achieved—that is, more than 99% after 1950.

This survey, and related research, in the chrysotile production industry were undertaken because of the critically important need, expressed in 1964,[1] for studies to compare the pathogenicity of the main asbestos fibre-types. A survey[18] of the much smaller Italian chrysotile mining industry has yielded findings very similar to our own; unfortunately, no comparable observations have been made on crocidolite or amosite production. Nor have there been any reports on mortality after exposure to single asbestos fibre-types in manufacturing or application, in which exposure was measured in more than duration. Two small factories working with chrysotile only were studied by Elwood and Cochrane[19] and Weiss,[20] a large plant with amosite only by Selikoff and Hammond,[21] and a small group with crocidolite only by McDonald and McDonald.[22] Because dust or fibre concentrations were not measured in these studies, comparisons of frequency of lung fibrosis and cancer cannot be made with confidence, although the evidence all points in the direction of more serious effects from the amphiboles than from chrysotile. The incidence of malignant mesothelial tumours, especially of the peritoneum, is so very much higher after exposure to amphiboles (and amphibole-rich mixtures) than after exposure to chrysotile alone, that differences in dust concentration are unlikely to explain it.[22–24]

As in earlier reports on the Quebec cohort, the patterns of gastrointestinal cancer are difficult to interpret. There was unquestionably a substantial excess in mortality from cancer of the upper gastrointestinal tract in men most heavily exposed. This excess was confined to Thetford Mines where most of the long and heavy exposures occurred. The exposure-response curves were far from regular, however, and it appears that some other important factors were also operating—perhaps selective, perhaps environmental. The SMR for cancer of the lower gastrointestinal tract for the complete cohort was 0·78 (table 6); nevertheless, there was some evidence of an exposure-response trend.

Our findings on laryngeal cancer are clear cut, although others' have not been so. There has been no excess in this industry, and there is no quantitative association with exposure; on the other hand, we find a direct relation with cigarette smoking.

Because an important current concern is the risk from concentrations of asbestos dust nearer to today's standards, we have re-examined our data for the 1904 men in the cohort employed for at least 20 years in the low and medium dust exposure groups. The concentrations to which these men were exposed (see table 4 and footnote*) averaged 6·6 mpcf, or perhaps 20 fibres/ml, and thus were much above anything permissible now. Nevertheless, as can be deduced from table 7(d), the total mortality in the study interval was 620 deaths, and the SMR was 0·94. This may well be a true healthy worker effect but not all cause-specific SMRs were below unity. Indeed, there were excesses for pneumoconiosis (10·3 excess deaths, leading to χ^2 on the usual basis, and with one degree of freedom, of 159·27), for lung cancer (6·4, $\chi^2 = 0·99$); cancer of oesophagus and stomach (1·1, $\chi^2 = 0·06$); "other" cancers (1·7, $\chi^2 = 0·06$); respiratory tuberculosis (1·3, $\chi^2 = 0·17$); and stroke (1·8, $\chi^2 = 0·07$). Apart from pneumoconiosis, these values of χ^2 are so low, even for lung cancer (where the associated p-value is 32·0%), that the observed excesses do not reach conventional levels of statistical significance. Moreover, the lung cancer SMR for the low dust exposure group (1·21) was higher than that (1·08) for the medium exposure group; only the greatly enhanced SMRs for those with high and very high exposure allow the conclusion that there was a response to exposure. Nevertheless, the lung cancer SMR for all 1904 men was 1·15, in close conformity with that which might be predicted from the figure (around 1·20), or the relative risk of 1·16 from the fitted line (Berry, G, unpublished). By their nature, epidemiological surveys, however large, cannot achieve greater precision than the one described here. Hence the clear importance of deciding whether a linear exposure-response model should be adopted, if only for practical reasons.

This survey was made possible by the contribution of many people and agencies, in private or official capacity. We would mention, in particular, Mmes M Beauchemin and F Proulx for their work in maintaining contact with ex-employees, Dr J M Fredette for help in finding death certificates, and Mmes M Gauthier and C Tessier for coding them. We had the active co-operation throughout of the mining companies and the several trades unions with members in the industry. Grants toward the cost of the research were made to McGill University and to the London School of Hygiene and Tropical Medicine by the Institute of Occupational and Environmental Health of the Quebec Asbestos Mining Association.

MEDICAL PROGRESS

THE PATHOGENESIS OF ASBESTOS-ASSOCIATED DISEASES

John E. Craighead, M.D., and Brooke T. Mossman, Ph.D.

ASBESTOS is one of our most useful minerals. Over 3000 manufactured products of contemporary importance contain it. Asbestos is employed in construction materials because it is resistant to thermal and corrosive destruction and increases the tensile strength of the product. These properties are also the basis for the use of the mineral in friction equipment and in a wide variety of consumer items requiring a relatively inexpensive insulation material that is light and subject to molding. Since the turn of the century, about 3×10^7 tons of asbestos have been used in construction and in the fabrication of manufactured goods in the United States. At present, several million Americans are employed in industries that use asbestos products, and countless millions of American citizens are exposed to asbestos cryptically in the course of their daily lives.

Public concern over the effects of asbestos on health is mounting. Although a total ban on its use in this country has been proposed, most would agree that asbestos cannot be replaced expeditiously in many products. Litigation based on personal injury consequent to pulmonary fibrosis and cancer is an increasing problem for companies involved in the manufacture, use, and distribution of asbestos. About 12,000 suits have been brought against 260 companies by workers, their families, and members of the general public.[1,2] The spectrum of liability has now widened to involve the federal government for alleged negligence in establishing adequate environmental standards.

This review summarizes our current knowledge of the adverse effects of asbestos on health and provides a perspective on the pathogenetic mechanisms of the diseases associated with exposure. Since there are several different mineralogic types of asbestos, we will attempt to assess the extent to which findings with one type can be applied to another. Detailed analyses of the issues addressed in this paper have been published elsewhere.[1-6]

MINERALOGY

Asbestos is not one mineral but a family of fibrous hydrated silicates that are divided on the basis of mineralogic features into two groups: the serpentines and

---

the amphiboles (Fig. 1). The term "asbestos" refers to the commercial product after mining and processing and is not a mineralogic designation. Although the length:width ratio of the mineral fiber known as asbestos is by definition ≥3:1, the individual fibers making up the materials used in commerce vary substantially in width and length (Fig. 2).

Chrysotile is the only serpentine of commercial importance. It is composed of pliable, curly fibers made up of fibrillar subunits. These fibrils are arranged in pseudohexagonal arrays composed of silicon oxide sheets formed into scroll-like structures. The magnesium ion, which imparts a strongly positive charge to the fiber, is an integral component of the lattice.

The amphiboles are straight, rodlike fibers consisting of double chains of tetrahedral groups having a basic silicon oxide composition and linked by one or more cations. The amphiboles differ from chrysotile in both physical and chemical makeup. There are several types of amphibole, but crocidolite and amosite are the two minerals of major importance.

Although an asbestos type is classified on the basis of its mineralogic characteristics, the products of different mines are not necessarily the same. Moreover, a commercial type of asbestos is not always mineralogically pure. For example, Canadian chrysotile contains small amounts of an amphibole fiber, tremolite. In addition, industrial grades of asbestos are contaminated with extraneous inorganic and organic substances that are acquired either naturally or during processing.

Deposits of serpentine and amphibole are ubiquitous in the crust of the earth. Outcrops are found in many geologic formations and probably account for the mineral fibers commonly found in surface water. Asbestos is also found with other minerals of commercial importance, such as the iron ore taconite and industrial-grade talc. Canada and South Africa are the major suppliers in the western world, although mines of limited commercial importance are found in many countries. In the United States serpentine and amphibole minerals are distributed widely in geologic strata, but only two relatively small mines in Vermont and California are active. The amount of asbestos produced in the Soviet Union and the People's Republic of China far exceeds that extracted in the West.

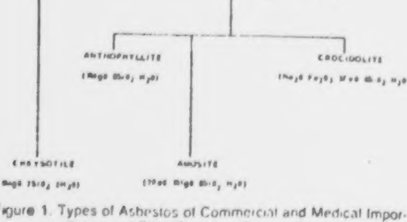

Figure 1. Types of Asbestos of Commercial and Medical Importance and Their Chemical Compositions

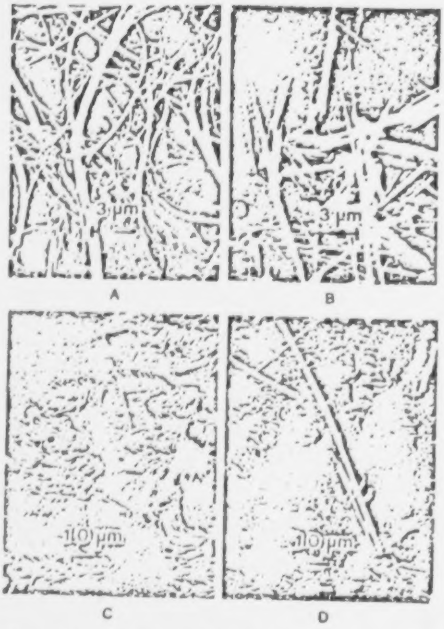

Figure 2. Differing Structural Features of Serpentine (Chrysotile) and Amphibole (Crocidolite) Asbestos.

These scanning electron micrographs of International Union against Cancer reference samples of chrysotile (Panel A) and crocidolite (Panel B) asbestos illustrate the heterogeneity of fibers in both length and diameter. Micrographs of the hamster tracheal epithelium after exposure in vitro to asbestos illustrate the curly, pliable nature of chrysotile (Panel C) and the straight, rod like form of crocidolite (Panel D). Note the dimensions of the fibers in comparison to the cilia. Photomicrographs were furnished by Mr. Craig Woodworth, Department of Pathology, University of Vermont College of Medicine.

Chrysotile currently accounts for over 90 per cent of the total asbestos marketed in this country and abroad. Crocidolite is the most widely used amphibole, but for reasons considered below, its commercial importance has decreased over the past several decades (Table 1).

Uses of Asbestos

The unique physical properties of asbestos dictate its continued use by industry, despite contemporary concerns about its effects on health. Although various man-made and naturally occurring substances have been developed as substitutes for asbestos, none

Table 1. Consumption of Different Types of Asbestos in the United States in 1978 *

Use	Type of Asbestos			Total Asbestos

*Modified from the data of Fagan.[7]

matches asbestos in providing tensile strength and moldability as well as resistance to fire, heat, and corrosion. In addition, many of the manufactured substitutes are comparatively expensive.[8]

About 25 per cent of the asbestos consumed in the United States is incorporated into cement piping for water mains and sewage lines. Over 320,000 km of pipe, containing about 10 to 20 per cent asbestos, is believed to be in use in this country. Asbestos-containing cement is employed widely in corrugated and flat sheeting, panels, tiles, and moldings for the construction industry. The mineral is used extensively in roofing and paneling and as a filler in architectural dead spaces. In the past, suspensions of asbestos were sprayed onto the structural steel of buildings to provide insulation and fire protection.

Because of its thermal stability, asbestos is well suited for use in friction material and is applied to molded brake linings. Although substitutes are being increasingly employed in disk brakes, as in the aircraft industry, a drum-brake lining for passenger cars that does not contain asbestos is not available commercially.

Textiles and plastics of a variety of types and applications contain asbestos in various concentrations, since it imparts resistance to fire and corrosion as well as tensile strength without inordinately altering the properties of the product or increasing its weight.

The countless additional industrial uses of asbestos are of concern because they can be overlooked by the manufacturer and unrecognized by the consumer. Although asbestos was known to industry before the turn of the century, its use in the United States increased dramatically during the mobilization that accompanied World War II. Asbestos was employed liberally in the construction and reconditioning of ships and in such diverse war industries as the manufacture of aircraft engines, combat vehicles, and gas masks. Although worldwide production has continued to increase since the war, consumption in this country has dropped substantially during the past decade. This trend can be expected to continue. Since the latency period for the diseases associated with asbestos is usually 20 years or longer, most patients seen today were initially exposed in the 1940s and 1950s, when control measures were often not rigorous.

DISEASES OF THE RESPIRATORY TRACT AND THORAX

The major pathologic effects of asbestos result from the inhalation of fibers suspended in the ambient air. The occurrence of disease is influenced by the type of mineral and the dimensions of the fibers that constitute it, as well as by the concentration of fibers and the duration of exposure.

Deposition and Transport in the Lungs

Timbrell et al.[9] studied the deposition of fibers of asbestos in the respiratory tract, using a cast of the porcine tracheobronchial tree. The diameter of the individual fibers proved important, length was a less important determinant.[10,11] Fibers with a relatively broad diameter are deposited in the upper respiratory tract, whereas thin fibers are carried peripherally into the parenchyma of the lung, where they lodge in the terminal airways. Bifurcations are common sites for fiber impaction, since patterns of air flow are altered at these sites.

The shape of the fibers also has a role in transport. Aerodynamically, chrysotile has a relatively large theoretical cross-sectional diameter because of its curled configuration. Thus, fibers of this type tend to be deposited more proximally than the needle-like amphiboles, which are transported more readily to the periphery of the lung. These theoretical and experimental considerations have been verified by analyses of the lungs of rodents experimentally exposed to asbestos of different types.[12]

Three biologic mechanisms participate in the clearance of fibers from the lower respiratory tract. By far, the bulk of the dust is removed by the mucociliary escalator of the tracheal bronchial tree, and the material is either expectorated or swallowed.[13-15] In the peripheral airways, short fibers are ingested by macrophages, and at least some of these cells probably migrate across the wall of the bronchioles and acini.[16-18] Asbestos fibers are also taken up by the epithelial cells lining the airways and appear to move between cells of the mucosa.[18-20] This material accumulates in the interstitium and is carried to regional lymph nodes.[17] In general, short fibers are cleared more readily than long fibers,[17] which tend to be retained in the lumens of the respiratory bronchioles and the alveolar ducts.

About a third of the inhaled particles initially lodge in the distal airways. However, only about a quarter of this burden is retained in the respiratory tract one month later.[13] There are two phases of clearance through the tracheobronchial tree. About half the asbestos is removed within a few days. Subsequently, clearance continues for extended periods. The bulk of this material is excreted in the feces.[15]

A variety of extraneous influences such as cigarette smoke and air pollutants affect the clearance and intrapulmonary deposition of fibers. However, these factors are extraordinarily complex, in part because individuals appear to differ in their responses to inhaled dust.[21-29]

Asbestosis

Diffuse pulmonary fibrosis is the typical lesion associated with prolonged, heavy exposure to asbestos.[30] It develops slowly over a period of years and seems to progress in the absence of continued exposure to asbestos. Initially, fibrosis is found in and around the respiratory bronchioles and alveolar ducts, where relatively long fibers deposit. With time, the fibrotic lesion progresses in a seemingly centrifugal manner, so that increasing numbers of respiratory units are involved. Fibers of asbestos tend to accumulate preferentially in the lower lobes and adjacent to the visceral pleura. Fibrosis is usually prominent in these regions, and the pleural surfaces of these lobes are frequently thickened by a dense layer of fibrous tissue. In advanced asbestosis, the fibrotic pulmonary tissue contracts and is reorganized to form the new air space typical of the honeycomb lung.

Ferruginous bodies are the histologic hallmark of exposure to asbestos.[31-34] They consist of fibers coated by complexes of hemosiderin and glycoproteins and are believed to be formed by macrophages that have phagocytized the particles. Asbestosis can exist when ferruginous bodies are difficult to demonstrate in the lungs by light microscopy. On the other hand, ferruginous bodies can often be found in the absence of serious parenchymal disease.[35,36] Thus, their presence alone is probably not a stimulus for the proliferation of fibrous tissue. Although they have been shown to form from foreign inorganic and organic fibers of many different types,[37] ferruginous bodies in most human lungs have asbestos as a core.[36] For this reason, the structures are commonly known as asbestos bodies.

The number of uncoated fibers in the lung greatly exceeds the number of asbestos bodies in the tissue.[38,39] It is not known why some fibers are coated and form the typical asbestos bodies, whereas others are uncoated. Since uncoated fibers are usually difficult or impossible to demonstrate by light microscopy, lung tissue must be digested and the residue examined by either phase or electron microscopy in order to carry out qualitative and quantitative studies of the fibers. Whereas relatively long fibers (>5 μm) are found by light microscopical techniques, electron microscopy makes it possible to identify very small particles.[40,41] Thus far, attempts to correlate the extent of disease with either the number of asbestos bodies or the overall content of fibers in the lungs have been difficult, although fibrosis is usually evident when 10^6 fibers per gram of lung (wet weight) are present. Quantitative studies pose many problems and are only a crude measure of exposure, partly because many fibers are cleared from the lungs and others fragment to increasingly smaller particles with time.

Macrophages are a key element in the response of the host to asbestos. Whereas these cells phagocytize short fibers and remove them from the airways, they cannot encompass and transport the longer fibers. Although retention of these long fibers in the distal airways appears to be an important consideration in the causation of pulmonary fibrosis,[18,20] the pathogenesis of the lesion is not understood. Incomplete phagocytosis of asbestos fibers in the airways could result in spillage of lysosomal enzymes[42] and release of soluble fibrogenic factors from macrophages.[43] On the other hand, oxygen free radicals liberated by macrophages and other inflammatory cells might also injure lung tissue. This idea is supported by our observations that superoxide dismutase, an inhibitor of biologic oxidants, protects cultured respiratory epithelial cells from the cytotoxic effects of chrysotile (Mossman BT, Landesman JM: unpublished data). Chrysotile is cytotoxic in vitro presumably because the magnesium of the fibers interacts with the plasmalemma and damages it, along with lysosomal membranes of cells.[44,45] It is unclear whether this is an important mechanism of tissue injury, however, since pulmonary macrophages and epithelial cells in the lungs of animals exposed to aerosolized chrysotile fail to reveal ultrastructural evidence of injury.[18,19]

Other biologic phenomena may prove important in the causation of pulmonary fibrosis. Asbestos activates complement by the alternative pathway[46] — a reaction that may be expected to result in the accumulation of leukocytes in the tissue and the release of lysosomal enzymes. This observation is consistent with the finding of an acute inflammatory response in some early lesions.[30,47] Finally, consideration must be given to the possibility that asbestos stimulates the production of collagen by cells. When chrysotile is added to cultures of fibroblasts in vitro, the cells elaborate reticulin and collagen at an accelerated rate.[48,49]

Although the hypothetical mechanisms mentioned above could account for the deposition of fibrous tissue in the lungs, the pathogenesis of asbestosis in human beings remains to be established. The question may be moot, however, since modern environmental controls have dramatically reduced exposure in the work place. The dust concentrations permitted by current regulations will probably not induce substantial pulmonary fibrosis during the lifetime of an industrial worker.

Pleural Lesions

Plaques are curious lesions made up of hyalinized fibrous tissue located on the parietal pleura of the thorax, diaphragm, mediastinum, and pericardium.[50,51] They are usually but not invariably associated with exposure to asbestos.[30] Although the occurrence of plaques correlates with the duration and intensity of exposure, it is common to find lesions in the absence of obvious disease of the pulmonary parenchyma. Thus, relatively small amounts of dust can induce the development of plaques. These benign lesions do not appear to develop into malignant mesotheliomas.

Characteristically, plaques are located in the intercostal spaces on the anterior and posterior lateral aspects of the thorax and on the dome of the diaphragm at sites where the visceral and parietal pleuras approximate during respiratory excursions. The configuration of the plaques is highly variable. For example, on the chest wall they usually follow the contour of the rib, whereas on the diaphragm they are customarily either disk-shaped or geometrically shaped and have a nodular surface. Over time the lesions become calcified, permitting easy recognition on x-ray films. Although most of the available epidemiologic information is based on radiologic surveys,[52-55] it is not always clear in published reports whether plaques were differentiated from the fibrous lesions of the visceral pleura that accompany pulmonary asbestosis.

Since plaques are found most often in persons exposed occupationally to asbestos for extended periods,[54-56] their overall prevalence in the United States is low.[57] In Eastern Europe and Asia Minor the lesions are frequently found in older members of the general population who lack documented exposure to asbestos. The presence of fibrous minerals in soil and in local construction materials may account for the common occurrence of pleural plaques in these regions.[58-61]

Malignant mesotheliomas of the pleural and peritoneal cavities are considered pathognomonic of exposure to asbestos, although in many patients a history of contact with the mineral cannot be elicited.[62-64] These rare tumors are of particular concern from a public-health standpoint because they are thought to occur in persons who have had either transient or indirect exposure to asbestos.[65-67] The development of mesotheliomas as a consequence of casual exposure, however, is an uncommon event. On the other hand, the prevalence of the tumor in workers who have had heavy exposure over extended periods is about 2 to 3 per cent and has been reported to approach 10 per cent.[68,69] It is difficult to determine how often mesotheliomas actually occur, because the latency period is usually 20 years or longer and can often be as long as 40 to 50 years. Some suggest that an epidemic of mesotheliomas will appear in the late decades of this century, consequent to the exposure of large numbers of workers during World War II.

The pathogenesis of the pleural lesions associated with exposure to asbestos is not known, but it is a topic of considerable contemporary interest. Fibrosis of the visceral pleura, plaques of the parietal pleura, and mesothelioma probably develop by different mechanisms, although a rigorous defense of this conclusion would be difficult. As mentioned above, asbestos is deposited preferentially in the periphery of the lung after inhalation. It penetrates the visceral pleura and is carried in the pulmonary lymphatics to the pleural surface. One is tempted to attribute the fibrous lesions on the visceral pleura to irritation by the physical presence of fibers on or near the surface. This mechanism might also explain the occurrence of plaques in the parietal pleura. Alternatively, the lesions may represent an organized fibrinous exudate resulting from the physical movement of the lungs against the pleural surface of the thorax.

However, these hypotheses are not fully consistent with the pathological observations. For example, plaques are often found without fibrosis of the visceral pleura or adhesions between the pleural surfaces. In addition, the lesions are localized and do not occur in the apexes or in the costophrenic angles. The pathogenesis of the lesions cannot be defined at present, in part because plaques occur only in human beings and experimental models have not been developed.

Experimental studies by Stanton et al.[70,71] provide an intriguing basis for speculation about the pathogenesis of mesothelioma. The dimensions of the fiber, but not the chemical composition, were found to be the critical determinant affecting the development of tumors in rats. Long, thin fibers of a variety of types proved carcinogenic when introduced into the pleural space, whereas short fibers and those with a relatively broad diameter failed to induce mesotheliomas. These findings are consistent with epidemiologic observations documenting the relatively common occurrence of tumors in populations exposed to grades of crocidolite consisting predominantly of long, thin fibers and the rarity of tumors in persons exposed to the comparatively blunt, shorter fibers of amosite and anthophyllite.[65,72-74] A fibrous zeolite, erionite, has recently been associated with the occurrence of pleural fibrosis and mesothelioma in a rural area of Turkey where commercial mining of asbestos does not occur.[61] Since the fibers of this mineral do not possess the chemical properties of asbestos but are morphologically similar to crocidolite fibers, the observation is consistent with the experimental findings of Stanton and his associates.[70,71]

The basis for the development of mesotheliomas in the peritoneum is uncertain. Presumably, fibers of asbestos in the lungs are transported in lymphatics to the abdomen, where they have been recovered from lymph nodes and other organs.[75,76] Asbestos is also transported across the mucosa of the gut after ingestion.[77,78] Whatever the mechanism for entry of asbestos into the abdomen, it is assumed that the pathogenesis of the tumors in the peritoneal and pleural cavities is similar. Peritoneal mesotheliomas occur only in persons exposed to amphibole asbestos. The gradual disintegration of chrysotile in tissue may account for the relatively uncommon occurrence of mesotheliomas of both the pleural and peritoneal cavities in persons exposed exclusively to chrysotile.[79]

The mechanism of malignant transformation of mesothelial tissues is obscure. Surprisingly little experimental information has accumulated, although there is reason to believe that the lesions may be comparable to the foreign-body sarcomas induced subcutaneously in animals by sheets of plastic, glass, and metal. The cell of origin is not certain, since some tumors are made up of malignant serosal cells, whereas others have the histologic features of fibrosarcoma. Mesothelial cells phagocytize asbestos[80] and proliferate when exposed to asbestos in vitro,[81] but malignant transformation has not been demonstrated after exposure of cultured mesothelial cells to asbestos. Cocarcinogenic substances and cigarette smoke do not appear to be pathogenetic factors in vivo.

Bronchogenic Carcinoma

Epidemiologic studies have documented an association between bronchogenic carcinoma and occupational exposure to asbestos.[82-87] The prevalence of tumors is higher in persons working with the finished products (such as insulators) than in miners and millers. The severity of the pulmonary parenchymal fibrosis correlates with an increase in the number of neoplasms.[88,89] However, the incidence of tumors is also increased in asbestos workers who lack radiologic evidence of asbestosis.

Some controversy exists over the most common histologic type of tumor, but among persons with asbestosis, adenocarcinomas predominate.[90,91] The lesions tend to occur more frequently in the lower lobes in conjunction with severe degrees of fibrosis.[90] Atypical hyperplasia of bronchiolar epithelium and multifocal adenocarcinomas are often found in these sites.

A linear dose-response relation between the cumulative dosage of asbestos and the development of bronchogenic carcinoma has been reported in miners and millers of chrysotile in Canada[84] and factory workers in the United Kingdom.[85] In the former study, those at greatest risk were exposed to concentrations of asbestos in the air that were higher than the current regulations of the United States Occupational Safety and Health Administration permit. A higher carcinogenic potential for crocidolite than for chrysotile has been suggested by studies of occupational groups exposed to either type of asbestos or to the two in combination.[92] Mortality among chrysotile workers is increased 2.4-fold, whereas it is five times higher than normal among miners of both chrysotile and crocidolite.

Surveys of the smoking habits of insulators,[93] factory workers,[94,95] and miners and millers[96] have consistently shown that bronchogenic carcinoma is uncommon in those who do not smoke. Whereas there is only a slight increase in the prevalence of lung cancer among nonsmokers, heavy users of cigarettes (those smoking more than 20 per day) have an 80-fold to 90-fold greater predisposition to cancer of the lung.[93-96] Thus, the combined effects of asbestos and smoking appear to be multiplicative rather than additive.[97]

What is the mechanism of asbestos-induced carcinogenesis in the respiratory tract? A consideration of contemporary concepts of neoplastic transformation is appropriate in developing an answer to this question. As initially recognized by Berenblum, carcinogenesis is a sequence of events that can be divided into steps of initiation and promotion.[98] An initiator interacts with the DNA of the target cell — an event that can result in malignant change. The carcinogen either acts directly with the DNA of the cell or requires metabolic activation by cellular enzymes. A promoter is generally neither mutagenic nor carcinogenic, although it is required if the neoplasm is to develop. For example, if the skin of a mouse is painted with a small amount of a chemical carcinogen, such as a polycyclic aromatic hydrocarbon, tumors fail to develop unless a phorbol ester is subsequently applied to the site. Promoting substances cause cellular division and proliferation as well as biochemical changes in the cell that appear to be essential for neoplastic transformation.[99]

Although epidemiologic data link exposure to asbestos with bronchogenic carcinoma in human beings, the precise role of the mineral in the process has yet to be defined. Since asbestos is not a potent mutagen[100] and inconsistently causes chromosomal aberrations in cells,[101-103] a mode of action comparable to that of a classic chemical carcinogen is unlikely. It therefore seems more plausible to suggest that asbestos increases the susceptibility of epithelial cells of the bronchi and their branches to transformation by carcinogens in the environment.

What biologic mechanisms account for the synergistic carcinogenic effects of asbestos and cigarette smoke in the respiratory tract? A plausible hypothetical construct should be consistent with the apparent lack of a threshold in human beings and the occurrence of neoplasms in the absence of appreciable degrees of pulmonary asbestosis.

Asbestos has many of the properties of classic tumor promoters, such as the phorbol esters.[104] Proliferation and squamous metaplasia are induced in the respiratory mucosa of rodents in vitro.[105] Asbestos interacts with the membranes of cells[106,107] and induces the synthesis of the polyamines that accompany cell division.[108] Since cigarette smoke also contains a host of substances with promoter effects, the inhalants may act in either an additive or a synergistic fashion to enhance the susceptibility of the respiratory mucosa to carcinogens.

However, alternative mechanisms are worthy of consideration. Asbestos can be phagocytized by the bronchial epithelium and can be transported intracellularly both free in the cytoplasm and in phagolysosomes.[20] These fibers may serve as a physical carrier of the carcinogens in cigarette smoke to the basal cell, the presumptive progenitor of the neoplasms. Transfer of polycyclic aromatic hydrocarbons to and through biologic membranes occurs promptly and efficiently when the hydrocarbon is adsorbed to asbestos.[109] Thereafter, the hydrocarbons are converted by microsomal mixed-function oxidases to biologically active epoxides and diolepoxides, which can interact with the DNA of basal cells.[110] Another (but less attractive) hypothesis involves the alveolar macrophage, which phagocytizes asbestos in the airways and possesses the enzymatic capacity to convert polycyclic hydrocarbons to active metabolites.[111] At present, the mechanism of asbestos-associated carcinogenesis is unclear, although the mineral appears to act like a classic tumor promoter. The fibrous nature of asbestos is critical, since exposure to nonfibrous oxides of silicon (for example, quartz) and a variety of silicates is not associated with an increased risk of bronchogenic carcinoma in human beings.

Cancers of the Digestive System and Other Organs

Asbestos is implicated in the causation of cancer in the upper and lower gastrointestinal tract and the kidney.[112-113] Oropharyngeal and esophageal tumors occur more frequently in asbestos workers who smoke, whereas a direct relation between smoking and the development of carcinoma of the large intestine and the kidney has not been established.

Selikoff and Hammond[114] and Elmes and Simpson[115] have reported a statistically significant twofold to threefold increase in the prevalence of tumors of the digestive tract in insulators, factory workers, and shipyard employees. Other surveys have either demonstrated a smaller increase or failed to establish an association between exposure to asbestos and neoplasms in this system.[116] We believe that the evidence must be assessed cautiously because the associations thus far reported are relatively weak. Since death certificates are used to obtain data in most studies, it is possible that peritoneal mesotheliomas have been confused with metastatic carcinomas of gastrointestinal-tract origin.

The general population is exposed to small amounts of asbestos in drinking water, beverages, food, drugs, and agricultural products. Potable water often contains mineral fibers that are presumably derived from geologic deposits and refuse dumps. The finding of fibers of amphibole asbestos in the drinking water of Duluth, Minn., resulting from the disposal of taconite tailings into Lake Superior,[117] prompted investigations to determine the concentration and characteristics of mineral fibers in water supplies throughout the United States. Fibers with the properties of both serpentine and amphibole asbestos were found in over half the samples of water studied (Table 2). Thus, many Americans consume water containing asbestos-like minerals.

Table 2. Concentrations of Asbestos-Like Mineral Fibers in the Water Supplies of Selected but Representative Communities in the United States.*

City	Concentration
	no. of fibers >5 μm/liter
Atlanta	5.75
Boston	3.98
Duluth	1.72
Dallas	0
Kansas City, Mo.	0.07
New York	0
Philadelphia	16.95
San Francisco	0.60
Seattle	0.85

*Prepared from Table 1.2 in Levine.

Mineral fibers have been detected in the urine of residents of Duluth in numbers corresponding to the concentration of asbestos in drinking water.[118] Interestingly enough, fibers have been found in the glomeruli and tubules of rats exposed in inhalation chambers to synthetic fibers.[119] These observations suggest that asbestos migrates to the kidney after clearance from both the gastrointestinal and respiratory tracts. Whether this has an influence on the occurrence of tumors in the gastrointestinal tract is unknown.

When fed to laboratory animals, asbestos interacts with the mucosa of the gut.[78] Fibers enter cells of the mucosa and prove cytotoxic.[120] The experimental evidence strongly suggests that ingested asbestos is disseminated to abdominal organs by the lymphatics and blood vessels. This conclusion is supported by postmortem studies of occupationally exposed persons; these studies have demonstrated asbestos bodies and uncoated fibers in most major organs.[26]

How does the ingestion of asbestos induce gastrointestinal carcinomas in human beings? In efforts to address this question, rodents were fed large amounts of asbestos over extended periods. With one exception,[121] these studies failed to demonstrate an increase in the prevalence of tumors in the gut.[122-124] The possible synergistic effects of asbestos on the induction of intestinal neoplasms by chemical carcinogens has also been examined.[125] Intragastric administration of asbestos failed to augment tumor development in rodents fed azoxymethane, a recognized intestinal carcinogen.

The carcinogenic potential of asbestos in the gastrointestinal tract appears to be low. The pathogenetic basis for the purported increase in the prevalence of carcinomas in certain occupational groups remains to be established.

PATHOGENIC POTENTIAL OF ASBESTOS TYPES

As emphasized above, asbestos is not one but a family of fibrous minerals, each of which has distinctive physical and chemical characteristics. Minerals from various parts of the world and geologic formations often have dissimilar physical properties, even though they are classified under a specific mineralogic type. These differences are relevant to our understanding of the effects of asbestos on health, since the characteristics of the fiber have been fully defined in only a few epidemiologic and experimental studies. The problem of evaluating the effects of different types of asbestos on health is compounded by the common practice of custom blending of various minerals for specific industrial applications and the use of one type and then another, depending on availability and conditions of the market.

Since the serpentine chrysotile is used extensively in industry today, it is important to ask whether its pathogenic importance is comparable to that of the amphiboles crocidolite and amosite. These latter minerals are of historical importance, particularly since they were used widely during and immediately after World War II and are probably responsible for a substantial proportion of the disease occurring today.

Much current debate centers around the question of whether all types of asbestos possess the capacity to induce mesothelioma. Experiments in animals yield an affirmative answer, but the results of this work may not be applicable to human beings, since pathogenic potential and intrapulmonary transport of fibers are independent considerations. Of all the types, crocidolite is clearly the most strongly associated with the occurrence of the tumor. But there are interesting differences in prevalence, related to the physical character of this fiber type. For example, in Northwest Cape, South Africa, and western Australia, mesotheliomas occur commonly in persons with occupational or casual exposure to crocidolite.[65] The mineral mined in these regions is composed of relatively long, thin fibers. In contrast, mesotheliomas are rare in the Transvaal of South Africa, where the crocidolite fibers are much coarser.

Another amphibole, amosite, is associated sporadically with mesothelioma, whereas the tumor rarely if ever occurs in workers exposed to anthophyllite. Both these latter types are made up of relatively short, blunt fibers. A number of studies have been conducted in miners and millers in Quebec and Italy, where the serpentine chrysotile is extracted.[71,126] Although the results are debated, the bulk of the evidence indicates that chrysotile is not an important cause of mesothelioma in these workers.

However, the data from certain occupational groups, such as workers in the textile industry and insulators who are exposed predominantly but not exclusively to chrysotile, are not as definitive. The risk appears to increase as the mineral is processed or when dust concentrations cannot be evaluated critically. Unfortunately, most epidemiologic studies concerned with this important question are clouded by uncertainty because of the prolonged latency period of mesotheliomas. Considerable effort has focused on determining whether the various types of asbestos differ in their capacity to induce bronchogenic carcinoma and fibrosis of the lung. Unfortunately, there is no good answer to these questions at present, since dose-related differences in the prevalence of disease have not been established.

REGULATORY CONSIDERATIONS

No topic is more complex and subject to controversy than the establishment of criteria on which to base standards for air quality in the work place. Regulations are exceptionally difficult to develop, because it is necessary to use data on morbidity and mortality documenting disease retrospectively in members of occupational groups who have had heavy exposure either in the remote past or over a lifetime. The difficulties are compounded by the long latency period of asbestosis and the asbestos-associated cancers.

Although recommendations for levels of asbestos in the air of occupational settings in this country were formulated in the 1940s, it was not until 1970 that federal regulations were promulgated as a result of the passage of the Occupational Safety and Health Act and the Clean Air Act. The initial standard was based on the light microscopical count of fibers of a length of 5 μm, collected by mechanical means. A concentration of five fibers per cubic centimeter of air, averaged over an eight-hour period, was deemed permissible, with stipulations for transient excesses above that concentration. In 1976 the contemporary standard of two fibers per cubic centimeter was established, and more recently a level of 0.5 fiber per cubic centimeter has been proposed.

Is the current limit of two fibers per cubic centimeter sufficiently rigorous to prevent disease in the future? Is it appropriate to base regulation exclusively on determinations of fibers of >5 μm when the bulk of the dust in air consists of fibers of a shorter length? Because standards are based on extrapolations from data accumulated among workers exposed to relatively heavy concentrations of dust in the past, predictions must be based on analyses that assume that there are no thresholds below which the disease fails to occur. Within the ranges usually found in the occupational setting, there appears to be linearity in the dose-response relation, at least with regard to bronchogenic carcinoma. However, the likelihood that cancer will occur is influenced substantially by cigarette smoking, since the risk in the nonsmoker who has heavy exposure to asbestos is increased only a few fold. Thus, the risk for the nonsmoking asbestos worker is substantially lower than the risk for a member of the general population who smokes two or three packs of cigarettes each day.

The conclusion that asbestosis fails to develop below a certain threshold dosage is based on physical examinations and radiologic studies of workers and not on pathological examinations. By these criteria, it is probably impossible to be certain whether a fibrotic lesion in the lung is due to asbestos. With mesothelioma, the data are more controversial. Although a dose-response relation appears to exist, the threshold may be determined by the life span of the person exposed, because the latency period for these tumors is protracted. Since the problem cannot be answered with contemporary epidemiologic and experimental approaches, it must be resolved by practical rather than theoretical considerations.

APPENDIX C

NEW YORK DEPARTMENT OF HEALTH ENVIRONMENTAL AND EPIDEMIOLOGICAL SURVEY OF THE BROOKFIELD LANDFILL AND SURROUNDING COMMUNITY - PRELIMINARY FINDINGS

In January 1982, sewer line construction through the inactive Brookfield landfill caused the neighboring community to complain of odors and increased health problems. Based upon a small series of non-random interviews, it was estimated that many people complained of nausea, wretching, vomiting, burning eyes, sore throat as well as respiratory complaints. At the same time there was public disclosure of past illegal disposal of toxic wastes at this landfill.

The Department of Health (DOH) initiated an environmental and epidemiological survey of the landfill and surrounding community. The environmental survey was designed to examine air, water and soil as possible routes of exposure and identify any chemicals which might be an immediate health hazard to the surrounding community. The epidemiological survey was designed to determine whether people living close to the landfill had more medical complaints in the period from January 1982 to July 1982 than people living further from the landfill and whether these medical complaints constituted diagnosed medical illness.

Epidemiological Survey

The area chosen for study was the census tract 146.01 and a comparable census tract 132.02 was selected as the control area (see map 1). The study area was divided into 3 zones. A stratified random samples was drawn from the study and control areas using the Coles reverse directory of listed telephone numbers. Those households with no telephone or no listed telephone were excluded from the survey. 30% of the households with listed telephones were sampled in Zone I while, 15% of those with listed telephones were sampled in Zones II and III. 10% of the households with listed telephones were sampled in the control area. For the control area, randomization was done without reference to census blocks. If any household refused or could not be interviewed, the next household listed was selected as an alternate in the control area and for the study area the next listed phone on that block was chosen.

The questionnaire used in the survey was developed from information gained from informal non-structured interviews with residents of the community as well as suggestions made by the Centers for Disease Control, U.S. Public Health Service. The questionnaire was not pretested nor were the individual questions validated. The questionnaire was administered by DOH nurses and supplemented by a physician and a nurse graduate student. It was planned to validate all health complaints of survey respondents by obtaining a release which would permit review of their medical records by the DOH.

The results of the sampling described yielded 561 households to be interviewed. When compared with census data, it appears that 75% and 78% of the households in the study and control area respectively had listed phones. The interviewing was started in June and completed in 8 weeks. A total of 555 were done, 99 in the control area and 456 in the study area.

	Area Zone	Households	Individuals
	I	153	569
Study	II	123	467
	III	180	641
	Total	456	1667
Control		99	317
	Total	555	1984

When compared to the census, this represents about 20% of the population in Zone I where 30% of the listed phones were sampled and 10% of the population in Zones II and III where 15% of the listed phones were sampled. In the control area where 10% of the listed phones were sampled, about 8% of the total population was sampled.

Of the 555 households interviewed, 285 (51%) were original choices while 270 (49%) were alternate households. These substitutions were made because of refusal to participate or because of inability to reach the original choice. When the original interviews are compared by location, there are increased numbers of non-respondents at greater distances from the landfill. 58% of those in Zone I volunteered when first contacted, while in Zones II and III in the study area, 56% and 49% responded initially. In the control area only 39% of the originally selected households were interviewed. Slightly more calls on the average were required in the control area (3.3) to gain an alternate than in the study area (3.0).

The study area and control area samples were similar to the census data for these census tracts in mean age, sex and race. There were, however, differences in age distribution. Less people in the 25-29 year age group were sampled than expected in the study area. In the 55-59 age group in the control group, more were sampled than expected from the census data.

The comparison of the study sample and the control sample to each other revealed similarities in sex and racial distribution but significant differences in age and family size. The control area residents tended to be older on the average and have a smaller family size. The household in the control area also lived at their current address for a longer time, 12 years versus 9 years for study area households.

In the 6 months period prior to the survey, the people living in the study area reported visiting a doctor or other health care professional more frequently than those living in the control area. 45% for study area residents versus 25% for control area residents gave such a report, a statistically significant difference. The reported visits were for the following complaints: chest or breathing problems, ear, nose or throat problems, stomach complaints, nerve problems including headache and emotional problems. The people in the study area and the control area, however, reported seeing medical professionals with the same frequency for kidney muscle, heart, blood, gynecological and skin complaints.

People living in the study also reported more symptoms since the beginning of 1982 for which they did not see a health care professional when compared to the control. These symptoms included frequent headache, sore throat and nausea.

Those living in the study area reported more allergies than persons living the control area. There was no difference between the two groups in terms of reported bronchitis, sinusitis or asthma.

Individuals in the study area reported more days absent from regular activities than those living in the control area. In the past six months, they reported an average of 2.3 days of absence while the control area residents reported 1.2 days of absence from normal activity.

Comparisons have been made only between the study area households as a whole and the control area households up until this point. If trends are examined within the study area itself, the tendency is for Zone I (nearest the landfill) to show the higher rates in the most of the categories reported. Zone I residents had rates greater then persons in Zones II and III in 13 out of 20 measures for complaints for which health professional visits were made. Out of 23 measures of symptoms experienced in the last 6 months for which health professions consultation was not sought, 16 of these rates were higher for Zone I residents than Zone II or III. If chance alone were at work, these medical events would be expected to be distributed with equal frequency throughout the study area. The trend observed, concentration of reported complaints in the area closest to the landfill is statistically significant.

Less than 20% of the survey respondents who reported their family members as seeing a health provider complied with the request for a medical release.

The responses to the questions addressing perceptions of the respondents in the study area and the control area revealed some significant differences. Those respondents living in the study area were less satisfied with living at their present location. They perceived odors more frequently and believed their health was poorer than those respondents living in the control area. More study group respondents felt their family members' health had changed for the worse since moving to this location in comparison to the control area respondents.

Environmental Sampling

Air at several locations on Brookfield landfill and in the surrounding community was sampled for volatile ogranic chemicals to examine the potential for toxic exposure directly from the landfill. Water infiltrating basements in the community, surface water and leachate seeps on the landfill were sampled for volatile organic chemicals and heavy metals to examine the potential for toxic exposure from leachate. All drinking water on Staten Island originates in the City's upstate reservoir system and therefore would not be a vector for materials from Brookfield landfill.

Private non-potable wells in the vicinity of Brookfield landfill were sampled for volatile organic chemicals and heavy metals to determine if a leachate plume could be identified.

All samples were analyzed by gas chromatography/mass spectrometry in the N.Y. City Department of Health laboratories.

RESULTS

1. Air Sampling

Air samples were taken using charcoal collecting tubes and distilled water impingers.

2. Landfill Air Sampling - A total of 5 air samples were taken at 2 locations in or next to the sewer trench under contruction. In addition, a total of 6 air samples were taken at the 2 sites identified by the N.Y. City Department of Sanitation as possible sites of illegal toxic waste disposal.

Volatile organic chemicals were detected in only 2 of the 5 air samples taken at the sewer trench. A sample at 1 of the trench locations contained chloroform, benzene, toluene, tetrachlorethylene and ethyl ether. Ethyl ether and benzene were the predominant constituents found; the concentrations were 6.5 and 4.5 parts per billion (ppb) in air, respectively. The other chemicals were found at less than 1 ppb. A sample at the other trench location yielded only chloroform (0.03 ppb).

Air samples at only 1 of the sites of possible toxic dumping contained volatile organics. There only was chloroform at 0.01 ppb detected. No volatile organic chemicals were detected at the other site.

3. Neighborhood Air Sampling - A total of 8 air samples were taken at 4 different locations spanning the residential area immediately bordering Brookfield landfill (see map 2). These samples also span Zone I of the epidemiological health survey.

Volatile organic chemicals were detected in the air at only 1 of the 4 locations. Benzene and chloroform were found at or less than 0.02 ppb.

4. Background Air Sampling - A total of 8 air samples were taken at 4 different sites at an average distance of 2.5 miles from the landfill, to detect ambient levels of volatile organic chemicals at locations removed from the landfill.

Volatile organic chemicals were detected at each of the 4 locations. Both chloroform and benzene were found at every location at an average of 0.04 ppb and 0.03 ppb, respectively. Toluene at 0.01 ppb was detected at only 1 location. In all cases, the levels found were greater than or equal to those seen in the neighborhood samples.

II. BASEMENT INFILTRATE SAMPLING

Basement water samples were taken from the sumps in the houses identified by the local residential association as bordering the landfill and having a history of water collecting in the basements. In total 5 houses were identified and sampled.

Only 1 sample had any detectable amount of volatile organic chemicals (2.6 ppb chloroform in water).

3 of the houses were in Zone I and 1 was in Zone III.

III. LANDFILL LEACHATE AND SURFACE WATER

3 water samples were taken in or near the sewer trench under construction through the landfill.

1 sample in the trench yielded xylene and n-propyl benzene at 228.8 and 156.1 ppb, respectively. Toluene and chloroform were also found at less than 3 ppb. One sample of surface water near the trench showed chloroform at less than 1 ppb.

A total of 4 samples were taken from leachate and surface water in the vicinity of the 2 sites of suspected toxic waste dumping.

1 sample contained 330.2 ppb of pentane. The other sites had less than 1 ppb total volatile organic chemicals. Lead, at .04 ppb, was the only metal detected, found in one sample.

IV. WELL WATER SAMPLING

A total of 13 private, non-potable wells were sampled to determine if a plume of groundwater contamination could be detected. With one exception, these wells were neither in the health survey nor control area (see map 1.)

9 wells had detectable levels of volatile organic chemicals. The chemicals included tetrachloroethylene, 1,1,1, trichloroethane, chloroform, benzene, and toluene. All of these chemicals are commonly found in contaminated wells in Jamaica, Queens and are widely used both domestically and commercially. 6 wells had less than 5.0 ppb, 1 well had 32 ppb and 2 wells had greater than 300 ppb total volatile organic chemicals. Tetrachloroethylene was the chemical present in the 2 highly contaminated wells, both of which were 2.4 miles from the landfill. Heavy metals were not detected in any of the samples. The location of these wells, and the distribution of contaminant concentrations gives no indication of a plume of contamination in the area of these wells.

CONCLUSION

No route of exposure to contaminants could be identified by these environmental sampling results; however, the epidemiological survey did record increased reported medical utilization. Further study will clarify whether the increased medical utilization represents actual illness and whether associated agent(s) can be identified with emissions from the landfill.

CONTINUING ACTIONS

1. Physicians will be contacted for verification and documentation of medical illness in the surveyed residents who provided releases.

2. Health survey participants who did not provide releases initially will be recontacted and requested to cooperate.

3. A sample of children within the community near the landfill will be tested for sensitivity to specific allergens and for pulmonary function.

4. A program of air sampling will be instituted in the spring which will involve a greater number of samples per location for a longer sampling time.

PRELIMINARY REPORT

Brookfield Health Survey Report - Phase II

The first phase of the Brookfield Health Survey showed that in the first six months of 1982, 35.9% of the study group and 19.2% of the control group reported visits to physicians with complaints referrable to the following physical systems: eye-ear-nose and throat, chest, cardiovascular, gastrointestinal, neurological and psychological. (see Table 1) These complaints had shown a statistically significant difference between the study and the control groups and were chosen for intensive follow-up. (Hospitalization rates for this selected group varied little between the study zones and control area and was approximately 7%)

The purpose of the second phase of the Brookfield Health Survey was to confirm the residents' reports of illness and to determine the medical diagnoses and the frequency of visits.

For any individual with a complaint in one or more of the above categories, his or her medical records were sought. There were 659 such persons.(see Table 1)

Over a 4 month period numerous letters, telephone calls and home visits by Health Department staff resulted in 419 persons (63%) ultimately providing releases to have their physican and/or hospital records reviewed. In zone 1, 70% of those who were sought gave releases,in zone 2, 65.7%, in zone 3, 58.4% and in the control area, 48.4% . (see map 1)

With these releases secured, the 144 doctors who cared for the 419 patients were contacted. A questionnaire relating to the patients' visits and medical diagnoses for those visits was to be filled out either by the physician, his staff or Health Department personnel. (see Appendix 1)

Overall, the questionnaires for 328 individuals (79%) were completed. The percentage of completions was approximately the same for the study zones and control area.

A visit to the named physician was documented in the correct time period for 218 persons or 2/3 of the total. (This period was between January 15, 1982 and the variable date of the Brookfield Health Survey interview, sometime in the summer of 1982.) In the study zones 1,2,3 and the control area, 66%, 69%, 68% and 56%, respectively, of the survey respondents' visits were documented in the records of the physician named. This shows that the rate of confirmation of physician visits was somewhat less in the control area than in the study area. This supports the finding in phase I that the percentage of respondents reporting visits to a physician for a condition of interest was greater in the study zones than in the control area (35.9% vs 19.2%).

It should be kept in mind that not all physician visits were reported on the survey. An indication of this under-reporting was obtained by examining records of 63 family members who did not report a visit for a condition of interest. When the physician records of these people were reviewed 2/3 did have a visit in the correct time period for a condition of interest. It should be noted that these people were not chosen by random selection and are not counted in further analysis.

Of 218 individuals who had a documented visit to a physician in the first six months of 1982, 204 were in the study zones and 14 in the control area (see Table 2). For purposes of comparison between the study area and the control area the small size of the control group presents a problem.

The difference in average age between the study group and the control group was pointed out in the preliminary report. This difference persists in this phase of the study and is even more pronounced. (see Table 2) The zone 1 individuals average 19.8 years while the control group average 34.6 years. This disparity is accounted for by the larger number of children in zone 1.

For the 218 persons with a documented visit in the time period the average number of total visits to a physician varied from 2.0 in the control area to 2.5 in zone 1. This result shows a slightly higher average for the study area.

The average number of diagnoses for all conditions varies little among the study zones and control area. (Table 2)

Table 3 presents estimated rates of illness for the selected body systems as measured by the number of diagnoses of interest per 100 residents surveyed. The rate of illness is higher for the study group as a whole when compared to the control group; and zone 1, closest to the landfill, has the highest rate of all the zones.

The results of this phase of the Brookfield Health Survey validate the earlier phase I findings that the percentage of residents that visited physicians was higher in the study zones than the control area . It may now also be said that the estimated rate of illness was higher for the study group than for the control group.

The illnesses encountered however, do not seem to have been prolonged or complicated. This can be inferred from the following:

1) Once a visit was made to a physician, the study area residents had a slightly higher number of total doctor visits on the average than the control area residents ;these visits resulted in a similar average number of total diagnoses.
2) Among the persons with selected complaints the rate of hospitalization was similar for study zones and control area.

[illegible] Dr. [illegible] N.Y.C. Department of Health, [illegible] Street, N.Y., N.Y. [illegible]

A CRITIQUE OF THE EPIDEMIOLOGICAL SURVEY OF THE BROOKFIELD LANDFILL AND THE SURROUNDING COMMUNITY

The objective of this survey was to find out whether people living close to the landfill had a greater incidence of illness than those living further away. The study area, which is next to the landfill, was divided into three zones. Zone I is contiguous to the area, and Zones II and III further away. An area still further away was designated the control area.

In the first phase of the study, members of a sample of households were interviewed to find out which members of the household had medical complaints during the previous six months. In the second phase of the study, the personal physicians of those who had complaints were contacted to confirm the reports of illness and to obtain diagnoses.

The major findings of the survey were as follows:

- During the six month study period, 35.9 percent of the study group and 19.2 percent of the control group reported visits to physicians.
- Rates of medical complaints were highest in Zone I, the area nearest the landfill.
- The rates of diagnoses, as determined by contacts with physicians, were inversely related to distance from the landfill.
- Reported illnesses were not prolonged or complicated.
- Hospitalization rates were similar in the study and control areas.

Because of several important limitations of the study, these findings cannot be used to draw any firm conclusions regarding the effects of substances in the landfill on the health of persons who live in the surrounding areas. These limitations can be categorized as follows:

- Potential biases arising from high nonparticipation and nonresponse rates.
- Potential biases in the administration of the interview questionnaire.
- Excessive reliance on subjectively reported, rather than an objectively determined measures of incidence of illness.
- Possibly non-comparability between the study and control areas.
- Inappropriate use of tests of significance.

Each of these limitations is discussed below.

Nonparticipation and nonresponse rates

The households to be interviewed were selected by a stratified random sampling procedure, but high refusal rates were encountered in the households originally selected, ie, 42% in Zone I, 44% in Zone II, 51% in Zone III, and 61% in the control area. As a result, alternate households had to be selected until the required sample size was attained. The use of such a large proportion of alternates may not only have seriously disturbed the randomness of the sampling design, but may also have resulted in additional bias in the sample because of possible differences in the health status between those who agreed to participate and those who refused.

Another potential source of bias is the higher participation rates among persons living close to the landfill than among those living further away, as indicated above. Persons living close to the landfill may believe their symptoms and medical problems are caused by their proximity to the landfill. As a result, they would be more motivated than persons living in more distant areas to participate in the survey and report their symptoms. As a result, a person with a given symptom who lives next to the landfill would be more likely to be included in the survey than would a person with the same symptom living at a greater distance from the landfill.

Another serious potential for bias arose from the refusal of 36.4% of the 659 persons with medical complaints to give releases that would allow the investigators to review their physician and/or hospital records. In addition, of the 419 who gave releases, 328 questionnaires relating to their diagnoses were completed by their physicians. This represents a nonresponse rate among the physicians of 21.7%. Moreover, only 218 of the 328 visited a physician during the study period. Thus, of the 659 persons reporting complaints, documentation of physician visits and diagnoses were obtained for only 218, or about 33%.

The interview questionnaire

There were two potential sources of bias in the administration of the interview questionnaire. One is respondent bias and the other is interviewer bias.

Respondent bias could have arisen among persons living in the areas close to the landfill. Having been informed of possible health hazards from substances in the landfill, they would probably have a more heightened awareness of symptoms than would persons living further away. Also, they would probably attach greater significance to pain and discomfort, and thus would more likely report them to the interviewer.

Interviewer bias could also have affected responses to the questionnaire. Since the interviewers obviously knew how far each respondent lived from the landfill, they may have, consciously or unconsciously, administered the questionnaire in ways that might have tended to elicit more positive responses among persons living close to the landfill.

In properly conducted epidemiological studies, where personal interviews are used to obtain data, attempts are made, where feasible, to conduct the interviews "blind"; that is, where the interviewer does not know which respondent is exposed or not exposed to the substance or substances under investigation. Even objective measurements, such as blood pressures and electrocardiograms, taken and interpreted by physicians, are done blind in properly conducted studies.

Blind interviews were probably not feasible in this study, but this potentially important source of bias should have been mentioned in the report and qualified the inferences drawn from the data.

Reliance on subjectively reported illnesses

In the first phase of the survey, interviews were conducted to identify persons with medical complaints. In the second phase, physicians were contacted to verify the complaints and obtain diagnoses.

The use of information from physicians, however, does not remove the biases that could have arisen by identifying ill persons through subjective interpretations of symptoms by the survey respondents. For reasons discussed above, the closer a person lived to the landfill, the more likely it was that he or she would participate and report symptoms. Getting information from physicians from a biased selection of patients does not remove the bias.

In this regard, it is interesting that the complaints for which there was a higher rate in the study area than in the control area were predominantly functional disorders, such as breathing problems, stomach complaints, headaches, and emotional disorders. Since these may be psychogenic in origin, their etiology may include an hysterical component, generated, perhaps, by anxiety aroused by reports of health effects from the landfill.

On the other hand, study and control areas did not differ in indices of illness derived from objective measurements or observations. One of these was the incidence of organic diseases, such as kidney, muscle, heart, blood, and gynecological disorders. The other was the frequency of hospitalization, which was about 7% in each area.

Comparability of the study and control areas

Samples drawn from the study and control areas were compared with respect to age, sex, and race, but no comparisons were made regarding socioeconomic characteristics of the areas. It is well known that, for many diseases and risk factors for diseases, incidence rates are inversely related to socioeconomic status. For this reason, the investigators should have compared the study and control areas with respect to such socioeconomic indicators as median income and educational attainment, and to have taken these factors into account in the interpretation of the data.

Information in the report suggests that the socioeconomic status of the control area was higher than that of the study area. One indicator is the fact that the study area is near the landfill, making it more likely that it would be inhabited by lower income people. Also, it was noted that the control area residents tended to be older and have a smaller family size, two indicators of higher socioeconomic status.

Thus, if in fact the residents of the study area were in a lower socioeconomic level, a higher rate of illnesses would be expected.

Tests of significance

Tests of significance were done when certain rates were compared between the study and control areas. These tests assume random selection of subjects from the population to which inferences are to be drawn. Since randomness was lost because of large nonparticipation rates, these tests cannot properly be used to infer differences between the study and control areas.

Conclusion

This study does not establish any causal relation between substances in the landfill and medical complaints. However, the limitations of this study, as important as they are, do not exclude the possibility that substances from the landfill could have affected the health of residents who live near it.

To determine whether they have been affected would require a different way of measuring the prevalence of illness in each area. It would be preferable to assess the health of each individual in the sample by a health examination given by a physician or other health professional. The information gathered in the survey should also include smoking habits, dietary patterns, alcohol consumption, socioeconomic characteristics, and other potential confounding factors.

If such a survey does establish higher rates of illness in the study area, and if these higher rates cannot be explained by confounding or by biases arising from nonparticipation, the survey would provide suggestive evidence of adverse health effects from substances in the landfill.

Mr. **Molinari.** I would like to turn, if we could, to the problems we heard yesterday related by an attorney who was representing a victim of toxic waste exposure. The lawyer, who apparently handled a number of such matters, narrated the difficulties that are presented to an attorney who has a client who appears to have a very serious problem, occasioned by the workplace. He related to us—and I recall the term—almost insurmountable difficulties in trying to establish with scientific certainty the causal relationship: the fact that, indeed, that condition was caused on the job. And he was talking about a client who had incurred expenses—let's not talk about the personal injury value, but expenses of over $100,000.

He also mentioned that only in the case where there were very severe injuries could any lawyer consider taking on a case, because they are usually on a contingent fee basis. Getting medical testimony is difficult; there aren't that many medical experts apparently available. The way he described it to us, the cost of medical witnesses is about $350 an hour, I think was the figure he said. He found he had to pay dearly for good medical experts.

So we get now, I think, to the heart of the problem: What should a person do who has a severe medical injury, believed to be caused by exposure. Then he goes to a lawyer. I practiced law, and I can tell you that there aren't many lawyers that would be very interested in taking on a case like that because of the difficulties in proving the case.

Yet; we know that there are—in my mind, there is no question—many, many thousands and thousands of people in this country who have suffered and are suffering from this kind of exposure. It was the attorney's suggestion that we in Congress consider changing the laws so that there would be a set of criteria established where, if you met that criteria, you had reached the stage where there is presumptive evidence that the injuries were caused by exposure to that chemical contamination. And then the burden of proof would shift to the defendant to prove that, in fact, the condition was not caused by that exposure.

Having heard testimony for a couple of days—and we will be hearing more—I see that as being a very serious problem. My colleague here, Mr. Sundquist, and I had a brief conversation before where we recognized the enormity of the problem, trying to establish causation, particularly when the industry keeps talking about scientific certainty.

Isn't there a midground that could be reached so that victims don't have to prove with scientific certainty their case? Indeed, if those conditions were in place today we wouldn't be discussing the issue. There would be enough lawyers around that would be jumping at the opportunity to litigate if they had the scientific certainty. But it does not exist. And I don't know how long it will be before we will reach that point in time.

But, in the meantime, there are these people who are, in my opinion, suffering and suffering severely and are entitled to be compensated. It seems to me that there is no other way; that we have to consider changing the law. And we have to reach a reasonable set of criteria at which the plaintiff has established a reasonable case, presumptive evidence.

There are different measures or standards we could talk about as necessary to reach that plateau. But once that plateau is reached, then the burden of proof shifts. The burden shifts to the industry who has the resources, the expertise, and the benefit of all these studies, so as to give that injured party a fair opportunity to seek redress for personal injuries.

I would like to receive your comments, Dr. Karrh, as an industry representative.

Dr. KARRH. All right, sir.

Mr. MOLINARI. I would expect that you are opposed to the concept, but maybe not as opposed as I think, because an early part of your testimony indicates that you do believe that the responsible party should pay. I have heard other representatives of CMA also speak in those terms.

Dr. KARRH. That is our position; that people who are victims, if it is shown they are victims, should be compensated. I don't think we have used the term "scientific certainty." I think earlier in my testimony—I would have to look at the transcript to be sure—I stayed away from that term. I did use the term "scientific probability based upon scientific evaluation of the data that was available." If it is determined with scientific probability that the condition or conditions are related to our actions or disposal practices or operations or whatever, then we certainly should be held responsible for those.

Mr. MOLINARI. What does a lawyer have to prove in that case?

Dr. KARRH. Not being a lawyer or judge, I am sorry; I can't answer that. I can tell you from a scientific standpoint we would like to be able to look at the data available, and from a scientific standpoint determine that there is most probably a causal relationship between the exposure and the result that occurs.

If you are talking about the testimony of Mr. Drew Ranier yesterday, if I could quote a couple of sentences, he said, in general, there are adequate remedies under Louisiana law for compensation of his client.

In another sentence, he said, "I would not propose a modification of the remedies available to Mr. Hollingsworth."

What we are saying is there may be a need for a change. We may, in a year, after we have gotten studies and the ATSDR has gotten studies, we may decide that there should be a change and come back to you and suggest you make a change. We are saying, let's not jump in and put together some type of legislative remedy when we don't know what we are remedying. Let's determine if we have a problem. What is the magnitude of the problem? What is the proper solution to the problem? And then remedy it.

Mr. MOLINARI. Since you want to quote from Mr. Ranier's testimony, I think it is only fair to tell you that he did orally make the suggestion to the subcommittee that the burden of proof be shifted under circumstances such as I outlined, because of the difficulties in proving a case by today's standards. If you take somebody that was as severely injured as the client that he had with him, Mr. Hollingsworth, yes, a lawyer might be willing to shoot crap on a case like that, because if he does come in with a verdict, he is going to come in with a big one.

But what about all the rest of the people, those who didn't suffer severely but are suffering and have suffered for a period of 1, 2, or 3 years or more? They don't have enough of a case to bring in a big verdict. An attorney is not going to take on that tremendous job, almost insurmountable, in trying to prove a case with the expectation of a modest verdict which would not compensate the attorney for the time put in or the individual who has been injured.

That is really what we are here to discuss. We are here to find out whether the injured party has adequate remedies under the law, as it currently exists.

Dr. **Karrh**. I think the 301(e) study group set up by Superfund—and it was a group of lawyers—made the recommendation that there probably needed to be a change in the current system, if their original presumption was correct. The original presumption was that there was a big problem out there and a large number of victims. They made that presumption and said if, in fact, there are large numbers, then we need to change the current system.

What we are saying is we don't disagree with that. Instead of making a presumption that there are large numbers, let's take a little bit of time—and we are not talking much time at all—and do what studies we can do to determine was that presumption correct and should there be some type of legislative change for that, rather than presuming that there is a problem and saying the system will fail. Let's get some indication of the magnitude of the problem, if it exists.

Mr. **Molinari**. What are your projections for the time lapse that would be involved?

Dr. **Karrh**. We will have the UAREP study that CMA is committed to proceed with, completed by 10 months from the time it starts. We think we can start in September. UAREP thinks they can start in September. That would be July. That is a year. This would be a study done totally independently of the chemical industry. The industry will be putting up, we hope, more than half of the amount of the study, and we hope we can get others, including environmental groups and others, to participate with us in this so that the chemical industry will not control the study at all. It will be an independent scientific study.

At the end of a year, we think we will have a pretty good idea of the magnitude of the problem, if a problem exists.

Mr. **Molinari**. Who is providing funding for the study?

Dr. **Karrh**. CMA is putting in $500,000 of the $1 million study. We are in hopes we can get other industry groups, environmental groups, governmental groups to come in with us and also help fund it.

Mr. **Molinari**. Then you are not sure you are going to be able to——

Dr. **Karrh**. We are not sure we will be able to get other groups to participate, but we are sure UAREP will start the study. If we can't get others to participate, then we will have to get as much out of the study as we can.

Mr. **Molinari**. The study will be completed next July?

Dr. **Karrh**. I cannot assure that the chemical industry will be able to pay for the full study if others do not participate with us.

But I can assure you we will start it and get whatever data we can out of it for the amount of money we put into it.

Mr. **Molinari**. Thank you.

Mr. **Levitas**. Mr. Sundquist?

Mr. **Sundquist**. Thank you, Mr. Chairman.

Dr. Karrh, I started the hearings with the premise that we didn't need more legislation. In spite of your testimony, I am still hopeful we don't need more legislation.

A few minutes ago you said we didn't have a problem with chemical dumps; that there is not a danger right now, July 21, 1983; there is not a health hazard there.

Is that correct?

Dr. **Karrh**. No, sir. I did not say we did not have a problem. I said the public perceived that there was a problem; that we have not been able to determine that there is a significant health problem from waste disposal sites, but that we need to look at it more thoroughly to determine if there is.

Mr. **Sundquist**. Although the public perceives it, as both you and my colleague mentioned during his questioning, you have not determined that there is a problem in your own mind; is that correct?

Dr. **Karrh**. Based upon the data that we have reviewed, we do not believe there is a problem that needs an immediate solution. We do believe we need further study.

Mr. **Sundquist**. How do you relate that to the Toone site, the problem there?

Dr. **Karrh**. I am not familiar with the lawsuit you are talking about.

Mr. **Sundquist**. I am talking about the site itself.

Dr. **Karrh**. Yes, sir. I can only go back to the epidemiology study——

Mr. **Sundquist**. Which showed from your standpoint that there was not a problem?

Dr. **Karrh**. It showed that there were some health effects the people experienced. When the cause of the health effect was found, and corrective action taken, the health effects went away. There is a problem at that site; the acquifers are contaminated. There is a problem there. That does not necessarily mean that there are large numbers of people for which some type of legislative remedy should be put forth so that they can be compensated.

From what you have told me today, it indicates to me at least that the current existing system is capable of taking care of the victims if there are victims there.

Mr. **Sundquist**. I want to move into that in a minute. That issue involved the pros and cons of changing the system; that the judicial system can or can not handle the problem.

But, again, I find your testimony inflexible in your failure to even acknowledge that we have a problem anywhere. I point to the Hardeman site; there is, by anybody's measurement, some poison in the ground or in the water.

Dr. **Karrh**. My testimony——

Mr. **Sundquist**. Whether it is 10 people who have been injured as a result, or 100, there still is a problem with some people. It may not be a big problem.

Dr. **Karrh**. My testimony says that—and I have said it repeatedly in answer to your questions—there is a problem there. The question we have though, is there such a problem, of such a magnitude—you used the number, whatever number may be affected?

Our testimony is that we don't know if there is a need for legislation. I would hope Congress would not pass legislation for 10, 15 or 20 people. But if there are numbers of people for which—similarly situated as those in Hardeman County, then there may be a need for legislation.

Mr. **Sundquist**. I hope we don't need legislation, either. But my problem is your failure to acknowledge that there is a problem anywhere. In your testimony, you say we have not yet established a probable relationship.

Dr. **Karrh**. Mr. Sundquist, I don't think that I have ever said there is not a problem anywhere. I just finished saying there is a problem in Hardeman County, TN. My testimony says that.

In response to your questions, I have said that four or five times today. That does not mean there is a widespread problem for which some sort of legislative solution is needed.

Mr. **Sundquist**. You are saying there is not a widespread problem?

Dr. **Karrh**. For which some legislative solution is needed at this time, based on the studies we have done. There may be a problem, and we think additional studies need to be done to determine is there a problem.

Mr. **Sundquist**. A few minutes ago I thought I understood—and maybe I misinterpreted when we were talking about the dumps—that you said there is not now a problem, but there could be one in the future.

Dr. **Karrh**. What I said was, based upon the data we have reviewed, we have not seen a widespread problem that requires some type of legislative remedy now. But we are in favor of cleaning up the dumps, because we think the dumps ought to be cleaned up, because they—in addition to the public perceiving a problem, there is a possibility that as long as the dumps are there, there could be a problem in the future.

So, yes, we are in favor of cleaning up the dumps.

Mr. **Sundquist**. There is a possibility of a problem in the future. What kind of problem?

Dr. **Karrh**. I have no idea. It would depend on the dump, what is in the dump, how many people are exposed, how are they being exposed, and what is the magnitude of it.

Mr. **Sundquist**. Is it a widespread problem potentially?

Dr. **Karrh**. Based on our review of the data, there is no widespread problem now. With the number of priority sites EPA has identified, if they were all to leak, there could be a widespread problem. But we are in hopes EPA will get on with the cleanup before they leak so we won't have a widespread problem.

Mr. **Sundquist**. How many of the dumps on the Superfund priority list now are leaking?

Dr. **Karrh**. I would have to refer that to the EPA people.

Mr. **Sundquist**. If you are telling me there is not a widespread problem, I don't need to ask EPA.

Dr. KARRH. I am saying there is no widespread health problem we can determine now.

Mr. SUNDQUIST. How can you determine that if you don't know how many dumps are leaking?

Dr. KARRH. Because we have looked at what little bit of health data are available and determined that based on that, there is not a widespread problem. But more studies need to be done.

Mr. SUNDQUIST. What did you say just a minute ago?

Dr. KARRH. I said several words.

Mr. SUNDQUIST. Just before this. You want to be quoted precisely and you want to give your total answer. I want to give you that opportunity. What did you say a minute ago about a small number, or what was the term you used on which you are basing your conclusion?

Dr. KARRH. I am sorry. I don't know in response to which question you are referring.

Mr. SUNDQUIST. Could you repeat the last question I asked and his answer?

[The record was read by the reporter.]

Mr. SUNDQUIST. So, based on the little bit of health problems now, you are not aware of a widespread problem with the dumps?

Dr. KARRH. I am saying there is not a widespread problem for which some type of legislative solution needs to be put forward based on the data we have reviewed; also using the occupational exposure data and drawing some inferences from that. But we certainly think further study needs to be done to determine if there is a widespread problem. We can only use the data available now and draw whatever conclusions we can from that.

Mr. SUNDQUIST. OK. Tell me the pros and cons, if you would, of the judicial system as it is now: Is it working? Is there a widespread problem or not, which should be addressed by some legislative activities that might come out of this committee? What are the pros and cons?

Dr. KARRH. I am not an expert on the judicial system at all. I am certainly not an expert on the legislative system, either. All I am saying is that before Congress passes some type of legislation, we would hope that they would look and see if there is a problem for which the legislation is needed.

Mr. SUNDQUIST. So your testimony today is not to tell us that we should or shouldn't pass legislation based on what we know; it is to tell us that Congress ought to find out more. You are not here to tell us we shouldn't have legislation?

Dr. KARRH. I wouldn't pretend to tell Congress anything, Mr. Sundquist. What I am here to say is that we have looked at what data are available and have decided that there is not an eminent problem that needs legislation at this time. But there is a need for studies at this time, and we want—we would like to have the studies done by ourselves and by the governmental agencies, and determine, is there a need for legislation.

Mr. SUNDQUIST. Do you feel that people in Hardeman County are going to be satisfied or be taken care of through the courts?

Dr. KARRH. I don't know. They obviously have used the remedy available to them, and that is the court system. That is the currently existing solution. So far we have seen no evidence that that system has failed.

Mr. **Sundquist**. But you are here representing industry, are you not?

Dr. **Karrh**. Yes, sir.

Mr. **Sundquist**. Your industry is opposed to any new legislation. I think, with good reason, that the Federal Government doesn't always satisfy everything that needs to happen through new laws. But I find your arguments weak in that you are saying we don't have a widespread problem with hazardous chemicals in dumps that have been located, or we don't have problems in Missouri where chemicals have been mixed with soil, when most everybody in the country, if you were asking the question, and the victims who have been before this committee, are saying there is a problem.

I would say to you and your industry that your failure to acknowledge that there is a problem is weakening your arguments that we don't need new legislation, and leading me to think we do. I think you are covering your head up with the blanket, turning up the electric blanket and assuming the prenatal position, instead of acknowledging the problem, and saying let's get on with it and figure out whether the courts are handling it or not.

Will they handle it in the future? Can they handle it in the future? Should there be a better plan? What I understand you to say is you want a year to determine that.

Dr. **Karrh**. What I am saying is that I agree with you. There is a public perception of a problem. I have said that repeatedly today. We have not yet determined that there is a scientific problem. We think that before we have some legislation, that may or may not address the problem that exists, we ought to determine what is the problem and what legislation is needed, if any.

Mr. **Sundquist**. There is a scientific problem in Hardeman County; I can tell you that.

Dr. **Karrh**. I really don't know what——

Mr. **Sundquist**. Ten or twelve. You said that yourself—10 or 12 people.

Dr. **Karrh**. I am not sure what you would like me to say. I will be glad—if you tell me what you want to hear from me, I will try to say it if I can. But I don't know what you want me to say.

Mr. **Sundquist**. You have been very consistent in your answers, as my colleague said. My frustration is that you refuse to acknowledge we have a problem with hazardous chemicals in the country.

Dr. **Karrh**. And the reason I refuse to acknowledge it is we haven't found it. If we find one, I will acknowledge it. We say, let's get the scientific data, and if there is a problem take care of it. But just because——

Mr. **Sundquist**. How long have we been dumping dangerous chemicals?

Dr. **Karrh**. I don't know.

Mr. **Sundquist**. What is the earliest? You don't have any idea?

Dr. **Karrh**. No, sir.

Mr. **Sundquist**. That is all my questions, Mr. Chairman.

Mr. **Levitas**. Dr. Riordan, your testimony, which is part of the record, describes the EPA risk assessment policy. Has that policy changed—I am going to give you two timeframes—during the period that Mrs. Gorsuch was administrator from the time previous thereto, and since Mr. Ruckelshaus has become administrator?

Dr. RIORDAN. Not to my knowledge, Mr. Chairman. But Dr. Anderson can answer that, I think, exactly.

Dr. ANDERSON. The answer is certainly no; not with respect to anything that is published. We are still operating from the 1976 interim guidelines for assessing cancer risk. We proposed guidelines for assessing genetic damage and they were never made final during the last 2 years. We did not change any of the guidelines during the last 2 years; nor has there been any issuance of a new Federal cancer policy to take the place of—such as it represented that kind of thing—the IRLG document.

I think within EPA the Carcinogen Assessment Group, which is the oldest risk assessment group in the agency, has certainly continued operating as it always has. It didn't alter course one bit over the last 2 years. It regarded animal studies the way it always did. Nevertheless, risk assessment is in its infancy and several refinements are being made on a rather continuous basis as we learn a little bit more about how to better assess the risk.

But I think the short answer to your question is that we really haven't changed. We are right now under Mr. Ruckelshaus' leadership looking at the need to advance our guidelines further and incorporate some of the refinements we have been doing by practice both in the cancer area and refining some of the other guidelines that we have commenced and not completed. He has asked us to make some recommendations so that we can make a decision whether we should do something more in this area.

Mr. LEVITAS. I saw, I think it was, a two-page memorandum from Dr. Hernandez, which would have been about the second half of 1981, in which he outlined criteria for taking action based upon risk assessment under the Superfund Program. I, unfortunately, don't have a copy of that document with me. But if you remember it, fine, and you can comment on it. If not, I will have to supply it to you for a subsequent comment.

Dr. ANDERSON. Mr. Levitas, I think what you are—I don't know the memorandum, but I think what we are talking about here is a separate process; that of deciding how to manage the risk. You assess the risk scientifically and say here is the scientific situation.

Mr. LEVITAS. That is correct.

Dr. ANDERSON. Then managing the risk is a separate decision that incorporates other considerations. I think there may well have been some differences in the way the risks were managed in the last 2 years versus the preceding 4 years, because I think essentially the record has been reviewed, and there were more actions in the preceding 4 years, and so forth. I think it would take some review I can't provide now.

Mr. LEVITAS. I think you are absolutely correct that the management of the risk question that arose in the context of these circumstances exists. At what point, and based upon what information and what procedures, shall regulatory or enforcement action be taken? Now, who in EPA could address that question for us?

Dr. ANDERSON. The various program offices, I would think, in each individual case. The agency has never adopted any guidelines for risk management. So you can't look at one set of guidelines and say this is exactly what they do. I would think you would have to almost go to each program and ask what they were doing before, and if they changed it.

Mr. LEVITAS. All right. I will retrieve my copy of that memorandum, and we will make it available to the appropriate people at EPA because it was a proposal for deciding when to take action. It followed the Dallas lead situation and in effect tried to institutionalize that decisionmaking process that occurred in the Dallas situation.

I want to compare that to the preexisting policy and whether there has been any change subsequently, since Mr. Ruckelshaus has come on. I am most interested in that.

Dr. ANDERSON. I would suggest referring it to the agency's policy office. Obviously, it is easier to have one point of contact. I think the newly named director of that office——

Mr. LEVITAS. That is Mr. Cannon?

Dr. ANDERSON. Mr. Cannon. Thank you.

Mr. LEVITAS. Thank you.

Dr. Riordan, I understand you have a meeting that you have to attend.

Dr. RIORDAN. That is not Mr. Cannon but Mr. Russell.

Dr. ANDERSON. I am sorry.

Dr. RIORDAN. Director of the Policy Office.

Mr. LEVITAS. Thank you, Dr. Riordan. You are excused. We appreciate you being here today. I found your testimony most interesting and informative.

If the rest of the panel could remain, I don't think we are going to be going much longer. In fact, we can't. I have got a 2 o'clock classified briefing I have got to get to.

Dr. Karrh, although neither your oral statement nor your written statement made reference to the fact that CMA thinks we should go forward with the cleanup of the dumps, you certainly have said that on several occasions in answer to my questions.

Dr. KARRH. Yes, sir.

Mr. LEVITAS. And the only problem that I have in relating that conclusion, for which I commend you, to your differing conclusion, when it comes to providing a mechanism for victim compensation, it lies in this sort of syllogism.

Leaving aside public perception, the reason that we should do something with respect to hazardous site cleanup is because the potential of public health risk exists. And it is more, presumably, than just a speculative or hypothetical risk. If these hazardous waste sites begin to leach out their materials and people in the adjoining area are contaminated with them, there is the potential—potential—potential of health exposure and adverse health consequences. So, therefore, we ought to clean up the dumps.

Now, if we are prepared to take action based upon that potential, then why shouldn't Congress similarly take action with respect to those people who are now presently and have been exposed to those same dumps?

Dr. KARRH. For one thing, we know the dumps are there, and that they, in the future, are likely to present a problem. We are not sure of the extent of the problem as far as victims are concerned. We know there are situations where there are victims. There are situations of few clusters of victims of various things.

The real question is, should we legislate some type of legislative remedy for a very small number with the anticipation that there is going to be a large number; or should we wait a very short period of time and determine what is the extent of the problem and then put in appropriate legislation that will address the extent of the problem?

It is not a matter of our saying that no legislation is ever needed. All we are saying is, "We know the dumps are there so let's clean them up because we know that they are there and, because they are likely to present a health problem in the future. "But do we have enough scientifically proven victims at this time that we feel that we know enough to put in the proper legislation and that legislation is needed?

Mr. LEVITAS. Wouldn't it depend on what the legislation consisted of?

Dr. KARRH. I am sure it would, to a large extent. But wouldn't what the legislation consisted of depend upon the number of people you are trying to cover with it?

Mr. LEVITAS. I am not sure that logically follows. Mr. Sundquist was making the point or was at least attempting to make the point, as far as your dialog was concerned, that there are people who have been affected by chemical exposure. And, as Mr. Molinari said, "The question is how do you prove it as a matter of fact?" And there are many areas of the law where, once a certain situation is shown to exist, then the burden of proof goes to the place where that situation originated to prove that they weren't responsible for it. The old example of storing water, impounding water in land; if it gets out, the person who is hurt by it can bring a lawsuit. And it is up to the person who impounded the water to prove that some act of God, or whatever, was actually responsible.

The same is true with certain dangerous materials, or the product liability area, as well. That type of approach could be taken, couldn't it, even without knowing the numbers of people who might be adversely affected by hazardous waste sites?

Dr. KARRH. Our feeling is that it is really reversing the current system where you have the guilty until proven innocent instead of the innocent until proven guilty situation. It may well be that that type of legislation is needed in the future. but we ought to know it is needed before we put it in.

Mr. LEVITAS. Well, I think that is true. I am not sure it follows that the need for that is based upon the extent to which the population is adversely affected. It could be addressed strictly from a legal jurisprudential point of view; that in any type of situation where the evidence of proof is in the hands of the person that manufactured, or stored, or disposed of a material, that since they have got the information, they are the ones who are in the better position to answer the questions as to responsibility.

But, as you have stated, you are not an attorney, and you don't want to get into that.

Dr. KARRH. That is correct.

Mr. LEVITAS. I will say, Mr. Sundquist, that next Thursday—next Wednesday, we are having a panel to address the questions of the sort that we have just been talking about, and we extended an invitation to the Chemical Manufacturers Association to have a representative on that panel. They declined for the consistent reason that since they don't perceive the present problem, therefore, they don't think it is appropriate to suggest solutions to the problem. So, you ought to be aware of that.

Japan—are you familiar with the system in Japan?

Dr. **Karrh**. No, sir.

Mr. **Levitas**. Japan has a system very similar to workmen's compensation, where if you live within a certain defined area near a hazardous waste site and manifest certain defined symptoms, then you qualify for compensation under this plan. But, by the same token, it has a limitation of liability.

Have you heard any discussion within your industry about that type of program?

Dr. **Karrh**. No, sir.

Mr. **Levitas**. I don't have any further questions at this point. We have got 5 minutes for Mr. Molinari to ask questions.

Mr. **Molinari**. I would like to address this to Dr. Riordan's representatives from EPA.

Yesterday, we heard from Mayor Leistner, who I see is in the back of the room. She talked about the people that lived in Times Beach, MO. EPA has agreed to a buy-out, totaling some $33 million. The State is matching with 10 percent. We heard, much to my shock and surprise, that there is no record being kept of the residents and where they are moving to so that they can be monitored.

Of course, it is a very simple point that some of these problems associated with the exposure to toxic or hazardous waste may not show up for some time. Yet, you have recently opened the Office of Disease Registry——

Dr. **Jason**. We have not. That is being done through CDC. CDC should also be keeping something of a log in terms of who the individuals are that they examine, the 140 or so they got samples on. They had something of a voluntary participation, which, of course, limits, you know, the actual useability of those kind of studies—who is going to volunteer, who is going to come. Even acknowledging those, they have 140 individuals they are expected to be able to follow.

Mr. **Molinari**. I am concerned about the chemical industry's view that when dealing with small numbers, the results of those samplings may not be adequate. We had something like, was it 2,200 people?——

Dr. **Jason**. 2,200 people.

Mr. **Molinari** [continuing]. Who resided there. I would ask you to go back to EPA, maybe CDC, and inquire of them as to whether it would be feasible to monitor, to whatever extent possible, those that you are able to locate at the present time, before you lose track of where they are.

[The following was received from Dr. Jason:]

Health Study at Missouri Dioxin Sites, Including Times Beach

Question:

At the Subcommittee's July 21 hearing on Hazardous Waste Victims Compensation, Mr. Molinari requested information on the health study that the Centers for Disease Control (CDC) is conducting for residents of Times Beach, Missouri. Among other things, he questioned whether CDC is establishing a registry of former residents to continue long-term health monitoring.

Answer:

In December 1982, EPA entered into an interagency agreement with CDC to conduct a health study and other health related activities at four dioxin contaminated sites in Missouri. The four sites are Times Beach, Shenandoah Stables, Minker/Stout residences and the Syntex Facility. The total amount of tne interagency agreement is $496,000 and its completion date is December 31, 1983. The newly created Agency for Toxic Substances and Disease Registry is responsible for conducting the study.

Activities under the agreement fall into three major categories:

1) Public health protection - recommendations on levels of 2,3,7,8 TCDD in soil to support decision on habitability, and on the need for further medical evaluation of residents.

2) Medical/Epidimiologic Evaluation - medical and laboratory examinations for population groups with highest environmental exposure.

3) Central Listing and Registory of Data for Exposed Individuals - a central file of people presumed to have been exposed to dioxin at the four sites.

A copy of the interagency agreement is attached. If you would like more detailed information on the scope and methodology for these studies, contact Dr. William Foege, Administrator, Agency for Toxic Substances and Disease Registry, Atlanta, Georgia 30333, telephone (329)236-3291.

4. NAME AND ADDRESS OF EPA ORGANIZATION

U.S. Environmental Protection Agency
Office of Solid Waste & Emergency
Response
401 M Street, SW, Wash., D.C. 20460

5. NAME AND ADDRESS OF OTHER ORGANIZATION

Department of Health and Human Services(HHS)
Hubert Horatio Humphrey Building
2nd and Independence Avenues, SW
Washington, D.C.

6. PROJECT TITLE

Agreement for reimbursement of funds obligated by HHS, Centers for Disease Control (CDC) for the investigation of complaints of illness among persons living in areas of Missouri which may be contaminated with dioxin.

7. SCOPE OF WORK

This agreement provides $496,000 to the Centers for Disease Control to cover obligations incurred for the health related activities described below. CDC will address health aspects of environmental dioxin contamination at four sites in Missouri. The sites are:
Arena 1 (Shenondoah Stables), Moscow Mills, MO; Arena 2 (Fill Areas 1 and 2); Imperial, MO; the Syntex Facility, Verona, MO; and Times Beach, MO.

This agreement covers the following site-specific activities:

1. Public Health Protection: At each site, CDC will provide recommendations or guidelines on the levels of dioxin (2,3,7,8-TCDD) in soil in order to support decisions on the habitability of affected areas, the need for relocation of residents and the need to initiate other public health activities such as medical evaluation.

Recommendations will be made in the context of cleanup strategies proposed by EPA.

CDC will develop a scientifically sound, practical working document for each site which will be reviewed by an appropriate panel, possibly including individuals from NIEHS, EPA, and outside toxicologists. Site specific recommendations may be provided (See continuation for Attachment I)

8. SPECIAL PROVISIONS

This agreement may be terminated by either Agency upon 30 days advance written notice.

1. Funding for this agreement will be made available to HHS by the Administrator for the performance of the site-specific activities described herein in accordance with section 111(c)(4) of CERCLA, as provided by Congress in P.L. 97-216, a 1982 supplemental appropriation.

2. CDC activities that pertain to ongoing Superfund responsibilities that are not site-specific in nature are funded under existing interagency agreements. (IAG# AD75F2A091) which provide funds for continuing staff support at HHS. Activities that have been proposed by CDC for investigation of potential dioxin contamination that are non-site specific, such as the development of questionnaires, providing ongoing technical support and advice to the State on dioxin in general; and
(See continuation sheet for Attachment II)

9. REPORTS

CDC will provide quarterly status reports to EPA by site for each category of activity (Public Health Protection, Medical/Epidemiologic Evaluation, Central Listing, Administration) which will contain:

1. An accounting of funds obligated to date and during the current reporting period.

2. A short narrative indicating progress made in the reporting period; and the current status of health-related activity.

(See Continuation Sheet - Attachment III)

12. EQUIPMENT-PROCUREMENT OF EQUIPMENT WITH EPA FUNDS IS:

☒ NOT AUTHORIZED ☐ AUTHORIZED ☐ SUBJECT TO THE FOLLOWING LIMITATIONS:

Equipment purchased will be inventoried in accordance with the supplying agency regulations. The supplying agency will be the accountable agency for all items of equipment costing $25,000 or less. EPA will be the accountable agency for all items of equipment costing over $25,000 or which form part of an integrated equipment system costing over $25,000. An inventory of equipment purchased will be submitted by the supplying agency annually to EPA on the anniversary of this agreement. A final inventory of such equipment will be submitted to EPA within 30 days of completion of the work and services under this agreement. Title to equipment purchased shall be vested in EPA whose decision concerning the disposition of the equipment shall be final. The agencies shall mutually determine the procedure for inventorying, accounting, and disposing of jointly funded equipment.

13. EQUIPMENT TO BE FURNISHED OR ACQUIRED

None

14. ESTIMATED COST

a. TOTAL ESTIMATED PROJECT COST	$ 496,000	b. AMOUNT TO BE FUNDED BY THIS AGREEMENT/AMENDMENT	$ 496,000
EPA SHARE	$ 496,000	EPA SHARE	$ 496,000
OTHER AGENCY SHARE	$ —	OTHER AGENCY SHARE	$ —

15. METHOD OF PAYMENT

☐ ADVANCE* ☒ REIMBURSEMENT ☐ ALLOCATION TRANSFER Not to exceed $496,000

*Unexpended amounts remaining at completion of the work will be returned to EPA.

16. BILLING INSTRUCTIONS:

Request for payment will be made by Itemized SF-1081 submitted to:

Environmental Protection Agency
Financial Management Division
Room 214
26 W. St. Clair Street
Cincinnati, Ohio 45208

CDC will cite the following site specific account numbers and DCN No. when requesting reimbursement.

	Account No.	DCN No.
Arena 1:	3TFA727F40	E2B034
Arena 2:	3TFA727F45	E2B035
Syntex:	3TFA727F51	E2B036
Times Beach:	3TFA727F61	E2B038

and will cite the following accounting information:

EPA Form 1610-1 (6-79)

Thomas O. Hammel FmD 12/30/82

Continuation Sheet - Attachment I

7. Scope of Work

in phases as data becomes available from EPA, and as such data are reviewed in the context of what is known about the route of exposure and the characteristics of the persons exposed.

Cost: Not to exceed $13,333

2. Medical/Epidemiologic Evaluation: As appropriate to each site, CDC will provide for medical and laboratory examinations for the group of people with the highest potential environmental exposure. These people (particularly if considered for relocation or when exposed chronically to high levels) should have a detailed medical and laboratory examination looking for the known or presumed health effects of dioxins as determined from findings in industrial settings or animal experimental studies. This preliminary assessment should be considered as a pilot evaluation to see if the most exposed people demonstrate health effects which, based on the best available clinical judgment, are consistent with dioxin exposure. Further evaluation of these or other groups can then be considered in the light of these findings.

CDC may enter into a cooperative agreement with the Missouri Division of Health to develop and implement a testing protocol. It is recognized that medical and laboratory tests cannot be definitive about the presence or absence of dioxin-related disease, but the best clinical judgment on an individual basis would be helpful in the determining the likelihood of possible effects in the persons tested.

For each site, CDC may also arrange to collect information from individuals relating to alleged dioxin-related health problems.

Cost: Not to exceed $200,000

3. Central Listing and Repository of Data for Exposed Individuals: Establish and maintain a central file of people presumed to have been exposed to dioxin at the sites listed in this agreement. As appropriate, CDC may enter into a cooperative agreement with the State of Missouri for establishing and maintaining this file. CDC will provide technical assistance to the State, as required.

Cost: Not to exceed $200,000

4. Administrative Costs: Department of Health and Human Services overhead factor = 20 percent

Cost: Not to exceed $82,667

Continuation Sheet Attachment II

8. Special Provisions

the development of a protocol to uniformally evaluate skin rashes which are alleged to be chloracne, will be funded from EPA/HHS existing interagency agreements.

3. While this agreement provides funding for the investigation of health effects at four sites, EPA may request CDC to perform similar activities at other sites with potential dioxin contamination where EPA may take removal or remedial actions. As appropriate, EPA will amend this agreement and provide additional funding to HHS, if required.

4. The Centers for Disease Control will in a timely manner share and consult with EPA concerning all data obtained and all proposed recommendations/ conclusions which are based on health activities taken under terms of this agreement. Data will be shared with Missouri health officials who are working with CDC under a cooperative agreement. Medical information about individuals obtained during their health evaluation will be provided to those individuals and/or their physicians at the request of the individuals. Interim and final reports, as well as recommended actions regarding health matters, will be issued only after review and consultation with EPA.

5. Reimbursements specified herein are contingent upon receipt, acceptance and approval by EPA of the quarterly status reports as required by this IAG.

6. CDC may obligate up to $124,000 for each site. On request of CDC, the EPA project officer can approve by memo shifts of funds among categories of activities and shifts of funds among amounts allocated for obligation at each site.

Continuation Sheet - Attachment III

These reports will be submitted to EPA on the 15th day of April, July, October and on project completion.

In addition to the quarterly status reports, CDC will provide to EPA documents/recommendations described in the Scope of Work.

All reports shall be submitted to:

William N. Hedeman, Jr., Director
Office of Emergency and Remedial Response
Environmental Protection Agency
Washington, D.C. 20460

Morgan Kinghorn, Comptroller
Office of the Comptroller
Emergency Protection Agency
Washington, D.C. 20460

Futhermore, CDC will retain detailed and accurate records by sites for all costs for which reimbursement is requested under this agreement. Such documentation may be required by EPA from time to time to support cost recovery actions. Additionally, documentation must be available for audit or verification on request by the Inspector General.

Dr. **Jason**. One other thing, Mr. Molinari. I have taken something of an interest in the bills, the concerns that you have. One of the things that I would wonder about is, when we start thinking of Love Canal, when we start thinking of Woburn, MA, it was really the citizens that organized and made a claim that there was something going on. We really depend upon an enlightened public to be able to realize a problem is actually present, that they think an exposure resulted in a medical health problem.

I think the idea of saying one way or the other that there is or is not a risk puts a great deal of responsibility on the people to recognize it. In the case of Woburn, we had a minister that recognized the problem. In the case of Love Canal, we had a small number of people who pushed the issue.

I can't speak for EPA's policy as one individual. But one of the problems we have is the one of who is going to be able to look at areas and say, does this represent a significant increase?—given the fact we are not always going to have enlightened people of the particular training involved in, let's say, Woburn, for example.

Mr. **Molinari**. I don't have very much time, but it seems to me that we certainly have at this point in time—or should have—people within EPA, at some level, who could follow these people and collect health data from them, assess it, compare it and then determine whether there is a problem. We shouldn't lose sight of these people whom we suspect may eventually have additional health problems.

I have one last question. We have a problem in my own area, where it is acknowledged that there were some 3 to 10 million gallons of a variety of chemicals dumped in a municipal landfill by organized crime and others. And the people in the nearby area are all complaining about problems, the same kinds of physical problems Dr. Carnow described and I described before.

I got about 50 or 100 people to go out into the field with questionnaires developed by a professional pollster. We had them spend 20 or 25 minutes asking all the questions to try to determine whether there was a health problem. We compared the answers against several other control groups living in the community further from the dumpsite.

Concurrent with that, the New York City Health Department did the same thing, only by telephone. We thought the results would be better if we went into the field with a professional questionnaire. What we did find was that there were well over twice the number of incidences of illness in that area as in any other area in the community.

Would that be considered scientific evidence by your definition?

Dr. **Karrh**. I would have to see the data myself, Mr. Molinari. I don't know exactly what you are referring to. Incidences of what? I would be more than glad to look at the data and give you an opinion based upon that.

I would like to point out one thing in response to your question regarding EPA and the registries. Had the Environmental Defense Fund, joined by the CMA, not sued EPA and HHS, registries would not have been set up. So we feel very proud of our role in it.

Mr. **Molinari**. You should be.

Dr. **Karrh**. I would be pleased to review that questionnaire, if you want me to.

Mr. **Molinari**. Assume we didn't make any mistakes in the testing techniques and that the survey shows the incidence of these problems is twice that of another area of Staten Island, we are talking about less than a half-mile square area here as opposed to the rest of the 57 square miles—and that the incidence of problems reported to the City Health Department and ourselves, two independent groups, reveals relatively similar results.

Would that be considered scientific data?

Dr. **Karrh**. It would be considered scientific data probably, but I think you would have to look at the data themselves and determine what you were finding and determine what the possible or probable errors are and see if they could enter into the final conclusion. I know Dr. Senser of the city of New York, who would be——

Mr. **Molinari**. Fine. I know the chairman has a very important meeting. I am grateful to all of you for coming here to help us with this very complex problem.

Mr. **Levitas**. Before I conclude, Dr. Carnow, let me furnish you a copy of a letter which a professional staff member on the Surface Transportation Subcommittee of this committee received from a law firm, Coburn, Croft, & Putzell, in St. Louis--at least, that is where their main office is—on behalf of the Monsanto Corp., asking for certain information from the committee under the Freedom of Information Act concerning you and your firm. And since I am advised by our counsel that the Freedom of Information Act in this regard does not apply to this committee, you ought to be aware of this in case you desire to provide that information.

Dr. **Carnow**. I am aware of it. I am aware of the fact that virtually everything I say is either recorded or monitored by this organization with which I am involved, in an adversarial situation.

Mr. **Levitas**. I would like to express my appreciation to everyone participating in today's hearings. I certainly learned a lot, I think, and I am not sure that I agree with all of the conclusions that the witnesses drew. And there are clearly some very strong disagreements between various points of view.

I am persuaded that Congress and the regulatory agencies, when we are dealing with public health, would—if we err, should err on the side of protecting the public health, even if we later find out that that was premature, rather than facing the possibility of seeing people exposed and victimized, and find out that they should not have been, and should have been compensated for it. And, in that regard, assuming the Congress were to follow your counsel, Dr. Karrh, and defer setting in place a new mechanism for victims compensation, based upon the outcome of that study or some other study, I would assume that if Congress were to do that, that the statute of limitations in that legislation would be adequate to cover those people who were victimized prior thereto, and could gain their relief, if they are still living, in the future.

So it may be that that approach would be a more reasonable one. That is something we are going to be kicking around for a long time. But it would also seem to me appropriate that, if that were done, to make a statute of limitations sufficient to make certain that no one has been jeopardized simply because we delayed, which is one of the possibilities that I know is being considered.

But I, on behalf of the subcommittee, want to express my appreciation to all of you for extremely informative and thorough testimony. It will aid us immeasurably as we proceed further.

Next Tuesday, we will resume these hearings with a legal panel consisting of Lyman Lundquist, an attorney with the firm of Heller, Irman, White, & McAuliffe; Mr. George C. Freeman, Jr., with the firm of Hunton & Williams; and Frederick Baron & Associates, all of whom will address the question of whether or not there need to be changes in the toxic tort area.

I think that that will follow very well from the testimony we have heard today from the medical and scientific experts who would address this subject.

Again, I thank all of you very much.

The subcommittee stands in recess until Tuesday at 10 o'clock.

[Whereupon, at 2:05 p.m., the subcommittee recessed, to reconvene at 10 a.m., Tuesday, July 26, 1983.]

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

TUESDAY, JULY 26, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 10:10 a.m., in room 2253, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Mr. Levitas. The subcommittee will please come to order.

This morning the Subcommittee on Investigations and Oversight of the Committee on Public Works and Transportation continues with its series of hearings on the matter of health and economic damages experienced by people exposed to toxic chemical wastes and the problems associated with their efforts to obtain full compensation for those damages, the so-called victim compensation issue.

Last week we heard testimony from some of those who have been affected by the presence of toxic wastes in areas where they live and work. We heard about the problems that their children and their neighbors have experienced from what they believe is the presence of a toxic chemical waste. We also heard testimony from a panel of medical experts, testimony that was most interesting and which indicated that there were obviously different points of view among those in the medical profession about the extent to which the presence of hazardous wastes in our water and soil and in the air may actually cause or pose human health problems.

I found that testimony to be most enlightening and while I have not formed any general conclusion based on the scientific portion of the testimony, it was clear to me that the difference in point of view that was expressed by Dr. Carnow and Dr. Karrh illustrates the difficulties in reaching judgments on this matter.

But with respect to the scientific portion of that testimony we will let the facts speak for themselves. I will simply observe that Dr. Karrh at least demonstrated admirably the quality of consistency even to the point of seriously damaging his credibility before the subcommittee.

In part, this difference in views appears to reflect the scientific uncertainties or limitations of traditional medical analytical techniques and the fact that frequently there may simply not be enough data or test results to answer questions about health impacts one way or the other. This, in turn, brings us to the questions we look to explore today.

Does this inability to prove or disprove with a high degree of certainty that hazardous wastes can seriously and adversely affect human health pose an insurmountable barrier to those seeking compensation for damages or harm they have experienced? Are the present remedies in the law adequate? Are the evidentiary and other requirements such that the legal system provides a reasonable vehicle of redress for those who seek compensation?

That last question, of course, is one which was explored in some detail by members of this panel and in particular by Congressman Molinari.

Just one last comment about Dr. Karrh's testimony. What I was referring to was his willingness to move himself and family into Times Beach and I was advised afterward that there is some property available for sale at good rates there and would urge anybody who shares that view to go in and make a killing right now.

With those introductory remarks, I would now recognize the gentleman from New York, Mr. Molinari.

Mr. **Molinari**. Thank you, Mr. Chairman.

I don't have any prepared text, but I would like to make an observation for the record.

Picking up where you left off, Mr. Chairman, last week we heard somewhat incredible testimony from Dr. Karrh, specifically about his willingness to live in Times Beach, MO, without the least bit of concern that his family might be exposed to dioxin. He predicated that feeling on the fact that there was no scientific evidence to indicate that exposure to dioxin on the part of human beings would pose any health problem whatsoever.

It was interesting to note at the conclusion of the week, we read a newspaper story of the NIOSH report, which I have not seen yet, but which is reported to indicate that for the first time there is some body of scientific evidence indicating that, in the case of human beings, there would be some harmful public health effects from exposure to dioxin.

I plan to get a copy of that as soon as possible; certainly that is something that we should be very aware of. Dr. Karrh spoke for the chemical industry. In particular, his testimony drew a comparison between workers in the chemical industry whose experiences, if in fact they don't have any harmful effects from working with chemicals, would demonstrate that residents of an area near a toxic waste dump similarly would not suffer health effects.

But now we are being told that, perhaps, dioxin has created some health problems for those in the industry. So that I would suspect that when we get the report, Mr. Chairman, if it does bear out what the newspaper accounts indicate, maybe Dr. Karrh would think twice about moving his family into Times Beach.

Thank you. I look forward to an interesting day of testimony.

Mr. **Levitas**. Dr. Rowland.

Mr. **Rowland**. I have no statement, Mr. Chairman.

Mr. **Levitas**. Before I call witnesses today, let me make the usual announcement. All testimony is taken under oath before this subcommittee. We request that the witnesses confine their opening statements to approximately 10 minutes, and then we will get directly into the questions after we have heard from the panel.

With that, the first witness this morning is Anthony Roisman, Trial Lawyers for Public Justice, Washington, DC.

Mr. Roisman, if you would please come to the witness table and raise your right hand.

[Witness sworn.]

Mr. LEVITAS. If you would take a seat. Identify yourself, your background, your interest and we will be pleased to hear from you.

I understand that the text of your testimony of June 28, 1983, before the subcommittee of the House Committee on Energy and Commerce has been submitted. Without objection, it will be made a part of the record. You will be speaking in part from that testimony.

TESTIMONY OF ANTHONY Z. ROISMAN, ESQ., TRIAL LAWYERS FOR PUBLIC JUSTICE, WASHINGTON, DC

Mr. ROISMAN. Yes; Thank you very much.

I am Anthony Z. Roisman, currently executive director of Trial Lawyers for Public Justice. I appear today as a private citizen and not in that capacity. Previous to this position I was the Chief of the Hazardous Waste Section in the Lands and Natural Resources Division at the Department of Justice. It was my responsibility to carry out the enforcement obligations of the Government with respect to the cleanup of hazardous waste sites.

In that context, and also in my current private practice in which I represent, among others, victims of toxic torts, I believe that I have something to contribute to this discussion which the committee has instigated on the issue of whether there should be victims compensation legislation in this area, and if so, what it should look like.

At the outset the debate seems to be framed on the question, is there really a problem?

I think that is a false issue and feel that it tends to deflect the debate. But because it seems to be the focus of so much hearing and testimony, I think it is appropriate to at least address it. First let me explain why I think it is a false issue.

If the Congress were to set up a victim's compensation scheme and there were no victims, the total transaction costs would be relatively slight. We would rather quickly learn that there was nobody who could qualify, and the Congress would not have expended a great deal of the Government's money. If, on the other hand, there is a problem, the scheme would be available to address that problem.

I feel that, at this point in time, at a minimum there is sufficient evidence available to suggest that there is a high probability that the problem not only exists but that it is quite widespread, and that if the Congress were to wait until the problem were even more apparent, the consequences in human suffering could be quite severe.

We know already as a result of congressional legislation, congressional investigations and Environmental Protection Agency investigations, that we have allowed the haphazard disposal of billions of tons of hazardous waste. We know that a substantial amount was placed in landfills and underground injection wells and other ways in which it is not totally under control. We know a lot of those dumps have leaked. In fact, an Environmental Protection Agency estimate was that as many as 2,000 of the dumps in the country may be serious enough to be classified as imminent and substantial endangerments to the public health.

Four hundred of those are listed in the Superfund list of sites which have high priority and deserve immediate cleanup.

Many of the dumps in the country have already contaminated ground water supplies, and ground water provides the drinking water for substantial parts of the population of this country.

Many people are already drinking that water or have drunk that water in the past, and a substantial number of them are sick.

The question that rises is, is that enough of a problem? Does that rise to the level at which Congress should act?

I submit that it does. In my own experience, I find that several times a month I receive telephone calls from individuals who say, we live near a dump. The dump has the following chemicals in it. The chemicals escaped from the dump; some have been found in my water. My child has this illness, my husband has that illness, my grandmother died of this other illness. I don't know but I think the dump had something to do with it.

Those calls that come to my office are but a small part of the total number of calls that trial lawyers across the country get from people who say, "Something is wrong, we are not sure what, but we want to get some kind of remedy."

The Association of Trial Laywers of America, which has 55,000 members in it, keeps an exchange called the ATLA Exchange. That exchange is available to the committee. The committee can ask the ATLA for the list of cases already filed in the toxic tort area where people are claiming they have been exposed to hazardous substances and those substances have caused them illnesses, property damage, or both.

The list is lengthy. The number of clients represented by it is quite substantial. The lawyers bringing the cases can only be compensated if they prevail, so there is a high probability that most of the cases have substantial evidence to support them. In fact, if they are filed in Federal Court, the lawyer who signs the pleading must attest to the fact that he has a good faith basis to believe that there is a substantive concern expressed which warrants recovery for his client.

All of this suggests to me as a lawyer that there really is a problem and a substantial problem. On the other hand you certainly have heard from some scientists, although not uniformly, that there really isn't a problem and that we won't know whether there is a problem until we have had many more years of study and analysis and many more autopsies in order to establish it.

I think it is best to appreciate this difference between the lawyer and the scientist by an anecdote.

If, at this moment, into the committee room were to walk a small two-legged bird covered with white feathers, waddling, making quacking noises, and you were to ask a lawyer in the room what do we have here, the lawyer would respond, looks like a duck, walks like a duck, quacks like a duck, it is a duck.

If you ask the scientists who want us to have more evidence, they would take out a knife, slice off the head of the duck, perform an autopsy and announce to all of us, it is a duck.

Now, the question really for the congressional people who are investigating this problem is, do we want to wait until all the ducks have had the autopsies done on them and find out that they were entitled to victims compensation or do we want to address the problem when all reasonable people would say it looks like a duck, walks like a duck, quacks like a duck, it is a duck.

I think, in terms of this issue, we know that we are not dealing with ducks. There are real victims out there.

Traditional barriers now exist to the recovery on behalf of those victims. But there are already moves afoot to deal with those problems. First, on the legal side, when you have a hazardous waste dump you end up with a substantial amount of waste in it from a variety of different sources. Traditionally, one might have difficulty trying to figure out precisely whose chemical got into the body of the victim and caused the damage.

Theories of joint and several liability, which provide that where the damage done to a person is indivisible from a number of different sources, the plaintiff is entitled to recover from one, the full amount of the damage and then allow that one to recover from all the other contributors, help to address the problem.

Strict liability deals with the problem that maybe the company at the time that the damage occurred tried to do the best it could and that may be a satisfactory answer as between that company and its insurance company, that company and some other company, but as between the company that puts the ultrahazardous substance into commerce and the victim who suffers from it, the law has said the liability should be strict so that the cause of action can prevail even if the plaintiff is not able to trace back and prove negligence.

Then there is the problem of causation. Once we know a particular chemical has gotten out of the chemical waste dump and has reached the plaintiff, does the plaintiff prevail if it cannot prove conclusively to a medical certainty that the cause of the illness was the particular exposure. There are some cases beginning to evolve that recognize that the concept of risk may be taken into account and that a plaintiff can recover if there is strong evidence that they have been exposed to a significant risk of an illness even if it cannot be proven conclusively that they have gotten the illness as a result of the exposure or that they will get the illness as a result of the exposure.

All of these legal developments move slowly. There are different courts in the country which are more likely to recognize them than others. But they are there. There is some development in that direction.

One of the issues that has to be faced in an investigation such as this one, is the issue of whether it makes sense for the Congress of the United States to recognize the justice of that trend and to ride that crest by writing legislation which adopts the end conclusion of where that litigation is going.

I submit that it is an appropriate step for the Congress to take when you are dealing with the appropriate level of damages.

The kinds of damages that people suffer as a result of exposure to toxic chemicals include property damages, direct human health effects which manifest themselves in large medical bills or loss of earnings or both. What we would call objective damages. They also suffer real pain and suffering, loss of consortium for wife or husband who loses their spouse, loss of companionship for a family that loses a child, and in appropriate cases the conduct of the company who has disposed of the waste is so egregious that punitive damages are there.

But all those damages, punitive damages, pain and suffering damages, loss of the intangibles, are really not objective damages. You cannot set a dollar amount and be confident that you had made it appropriate for every case for either pain or suffering, or punitive damages, or any of the intangible losses.

That suggests to me that there is a reason to have a system which has two separate tiers to it. One in which compensation is essentially guaranteed without fault on the basis of a fund of money created by the companies whose conduct has caused the problem in which individuals can come forward and subject to much modified rules of proof and much modified standards of law are entitled to recover for their objective direct undoubted losses, medical expenses, property damages, costs that are of that nature.

Then separate from that allow the private tort system which is evolving to recognize this problem, to continue that evolution and, where appropriate, to proceed to provide relief for the intangible damages, pain and suffering, loss of consortium, other intangible losses and, in appropriate cases, punitive damages.

The two-tier approach, as it is known and as you will hear from the 301(e) study panel that follows my testimony this morning, allows for both systems of justice to operate, both systems to take acknowledgement of the differences between the types of recovery available and the needs.

We are also seeing some modifications in the thinking about medicine as well as about the law. You have already heard from two of the proponents of different points of view, Dr. Karrh who represents the more traditional, let's do the autopsy on the ducks approach.

Dr. Carnow, who is a very famous and well-regarded medical professional who is looking at new ways of finding the evidence that there are toxic chemical damages in humans that can be traced directly to particular exposures and which themselves can be shown to be the precursors of serious illnesses in the human body, including cancer.

Those medical experts will become important parts both of the victims compensation scheme, and of the subsquent tort litigation which is followed in those cases where appropriate in the private bar.

Finally, and most importantly, I want to stress that this task from the victims' perspective is not an easy one. What we talk about easily here in terms of tracing the chemical from the dump site to the water supply and from the water supply to the victim and find within the victim the evidence of that chemical and the damage done to them, is an extraordinarily expensive matter. It is not done even with thousands of dollars but measured in tens or even hundreds of thousands of dollars of costs.

Any system that the Congress wants to set up which is designed to provide relief for the victims has to recognize that if the door to victims' compensation is open only to those with substantial wealth, it is essentially closed to most of those who are suffering.

What I have proposed and discussed in my prepared testimony which I submitted a couple weeks ago, is that the system should have a plateau of evidence, at a relatively low level, which entitles the victim who is seeking compensation to the resources necessary to develop the remainder of the evidentiary side of their case, that it means nothing to the victim to be told "if you can prove with a Dr. Carnow, and if you can prove with the most sophisticated toxicological evidence, and if you can prove with a groundwater monitoring survey that you were exposed to this particular substance as a result of leakage from this dump, we will give you recovery," but does not give you a way to have resources to do that, then there will be no recovery and no victims compensated as a result of it.

If, however, the plateau provides that the first compensation to the victim, which may be compensation not to one but perhaps to a 100 or 200 potential victims living in the vicinity of a leaking dump, if the first plateau provides the resources for the studies to be done to determine "Is this dump contaminating the drinking water supply or the air or the soil" and then second, through epidemiological work and the work Dr. Carnow does, whether or not certain individuals can be shown to have gotten their illnesses as a result of those exposures; if that work can be done first from the victims' compensation scheme, then the opportunity to make certain that true victims are compensated and that all victims are given the opportunity for compensation, will be guaranteed. Without it, the victims' compensation scheme will be nothing more than one more victimization of the victims.

Thank you.

[The statement of Mr. Roisman follows:]

TESTIMONY OF ANTHONY Z. ROISMAN, BEFORE THE SUBCOMMITTEE ON COMMERCE, TRANSPORTATION, AND TOURISM OF THE HOUSE COMMITTEE ON ENERGY AND COMMERCE

Mr. Chairman and members of the Subcommittee, my name is Anthony Z. Roisman. I am presently an attorney in private practice and among my clients are many families who are the victims of exposure to toxic substances that originated from hazardous waste disposed of in a manner which at the time of the disposal was characterized as "current industry practice" or "state of the art technology." I was previously Chief of the Hazardous Waste Section of the Land and Natural Resources Division of the Department of Justice. I appear here today to support this Subcommittee's longstanding effort to provide some form of compensation for the victims of state of the art hazardous disposal technology.

In 1976, when Congress enacted the Resource Conservation and Recovery Act (RCRA), it found that "disposal of solid waste and hazardous waste in or on the land without careful planning and management can present a danger to human health and the environment," that "inadequate and environmentally unsound practices for the disposal or use of solid waste have created a greater amount of air and water pollution and other problems for the environment and for health" and that "hazardous waste presents . . . special dangers to health." 42 U.S.C. 6901(b)(2)(3) & (5) (§ 1002(b)(3) & (5) of RCRA). Among the evidence Congress gathered prior to enactment of RCRA was the shocking revelation that persons living near the Love Canal hazardous waste dump in Niagara Falls, New York, had an abnormally high percentage of a variety of serious health effects and had been and were continuing to be exposed to significant levels of contamination from Love Canal.

By 1980 when Congress enacted the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA or Superfund) there was broad acceptance of the fact that hazardous waste not only can but already had caused serious and widespread health problems. By that time Love Canal had become the focus of public awareness of the dangers of hazardous waste and Congress referenced the studies showing increased levels of miscarriage and birth defects among the Love Canal families.

Today, seven years after the Love Canal disaster became a matter of knowledge, after enactment by Congress of two major pieces of legislation specifically addressing the hazardous waste problem and after it became obvious that Love Canal was not only a tragedy but the first signal of a nationwide health crisis, not a single victim of that tragedy has received any compensation for the health damages they suffered and continue to suffer. Nor have any other victims of hazardous waste been compensated for the damages they suffered—not in Times Beach, Missouri; not in Dallas, Texas; not in Midland, Michigan; not in Jackson Township, New Jersey; not in Hardeman County, Tennessee. To those who may consider being uprooted from your home, placed in motels and trailer camps, fed at diners and fast-food restaurants and paid a sum of money for your family home which is inadequate to enable you to purchase a comparable home as compensation, let them offer to trade places with the victims who have been so "compensated."

It is a cruel irony that the victims whose suffering produced the groundswell of support for legislative programs have yet to benefit from this legislation. Enormous pressures from the chemical, hazardous waste and insurance industries persuaded Congress in 1980 to duck the victims compensation issue in order to enact at least the clean-up provisions of Superfund. The Section 301(e) study mandated by that law has been completed and its diverse membership endorses the need for victims compensation legislation. This is legislation which cannot be denied and which has already been too long in coming.

As this subcommittee continues its deliberations on this legislation, several key concepts will emerge as pivotal. Today I will address some of these concepts.

First, where should the legal presumptions lie under the compensation legislation? In this world of imperfect knowledge we will inveitably have to face points of decision where we cannot be certain we will be right—but nonetheless a decision must be made. In no area is that concept more relevant than compensation for victims of exposure to toxic substances. Many distinguished scientists correctly note that our knowledge in this area is still limited and that it is often difficult if not impossible to prove to a scientific certainty that a particular illness was caused by a particular toxic substance which had its origin from a particular source. As I will discuss later, there are some exciting breakthroughs in this area which greatly expand our available knowledge, but for the moment let us accept the point put forward by these distinguished scientists. We still must answer the question what should society do in the face of this inadequate knowledge particularly when we do know as a matter of scientific certainty that some toxic substances do in fact cause some illnesses and that there are identifiable sources of such substances?

It is at this point, when society attempts to decide what action to take, that the controversy arises. Those who in some way have a connection with the production, use, disposal or insurance related to the toxic substances quite understandably argue that compensation to victims should not be allowed (at least not if they have to pay for it) until we know as a matter of scientific certainty that the substance caused the particular illness and had its origin from a particular source. These same interests make a similar argument against setting standards for pollution control and favor instead the continued exposure of persons to the polluting substances until the sheer weight of the body count establishes the scientific certainty which they demand. Congress has properly rejected this approach for establishing pollution control. It has realized that we cannot tolerate the use of the public as a guinea pig and thus hazardous waste and other environmental and health laws establish standards based upon avoidance of risk. The fundamental principle at work in these statutes is that while adherence to risk avoidance may unnecessarily control a pollutant or exclude a product the harm caused by occasional "over-regulation" is substantially less than the harm which would be caused if a highly dangerous pollutant or product were allowed to be widely distributed and the feared risk were realized. In short these laws place the presumptions in favor of human health over corporate profits.

Victims compensation laws should do the same. Once it is established that a person has a genuine illness which has been shown to be of the type caused by toxic substances the presumption should be that the person is a victim who is entitled to compensation. Once a particular source is identified at which the toxic substance was present, from which it escaped and that the victim was in an area which could be reasonably expected to be affected by the substance then the presumption should be that the source caused the victim's illness. If the source can establish that the illness was not caused by the substance or that it was not the source of the victim's exposure, then the source would not be liable. In short the burden of scientific certainty should be placed on the person best equipped—financially and technologically—to carry that burden. To place on the victim a burden of proof that the victim is financially incapable of meeting is to make a mockery out of the concepts of due process of law and equal justice under law.

This brings me to my second point. Obviously a potential victim must be able to prove something to be compensated by the system. How does the victim obtain that information? A properly taken and thoroughly analyzed well water sample will cost $1,000 to $3,000. Medical tests and diagnoses can add thousands more. A groundwater study to connect the local dump to the polluted well will run $25,000 and up, depending upon the complexity of the problem. Epidemiological studies to demonstrate that among those exposed to the toxic substances there is a statistically relevant increased level of the illness suffered by the victim will add $50,000 or more. Lawyers taking toxic tort cases are anticipating a minimum of $100,000 to $200,000 in costs just for gathering the scientific and medical information required to prove a claim.[1] Unless a victims compensation law addresses this problem, the law will be nothing more than a cruel joke—offering compensation to the handful of very rich people who happen to be living near a hazardous waste dump. Even presumptions cannot solve this problem but there are at least two approaches which I believe warrant consideration:

1. Establish a very low threshold standard for a victim to meet—i.e. illness of the type caused by a particular toxic substance and a possible source of the toxic substance in the area—and once the standard is met the victim will be entitled to fund compensated scientific and medical investigations. In any recovery by the victim the amount of these costs would be returned to the fund. In this example the compensation fund becomes a revolving source of financial aid.
2. When the same threshold is met either require the suspected source to pay the cost of investigation or to conduct, under independent supervision, the necessary investigations. In this example we extend to victims compensation the same standards used by the federal government in enforcing § 7003 of RCRA (the imminent and substantial endangerment provision) or in exercising its authority under § 3013 of RCRA (ordering data gathering by the source based upn a possible substantial hazard).

These are not exhaustive, but illustrative. The principal point I want to make is that the victims must have access to the financial wherewithal to prove their point or they will be certainly shut out of the system.

My third point relates to the role of the state common law system in providing redress to victims. I am a great fan of the common law because I believe it embodies the fundamental principle upon which this democratic society is based—justice. Unconstrained by statutory language and legislative history a court and/or jury deciding a case under the common law is basically asked to listen to the facts, decide where justice lies and render a judgment accordingly. Large corporations are not surprisingly frightened by this system because once the individual has the resources to prove his facts the corporate leverage of money, political influence and sheer power is gone and the two litigants are essentially treated as equals by the judge and jury. While I am not surprised that industry seeks to avoid this system of basic justice (such as urging Congress to adopt product liability or victims compensation legislation that will essentially eliminate the common law in that area), I feel it is important to realize what motivates that position.

At a conference on toxic torts two years ago, representatives of the chemical and hazardous waste industry urged adoption of a form of victims compensaton legislation that would essentially replace common law with a statutory scheme and their principle emphasis, echoed by the insurance industry, was unless such a scheme existed there would be no economic certainty. In short, the industry wanted to know up front what its liability would be so that insurance premiums and product prices could be established accordingly. Not only does this approach turn human suffering into nothing more than a budget item and encourage cynical judgments to let a certain number of people die because the corporation "can afford it" but it unfairly shifts all the risk of uncertainty to the public which does not know who will be injured and how seriously and who will die. Surely before we start giving economic certainty to those who cause these problems we should provide certainty to the public about the nature and extent of the harm that will be caused.

---

[1] These costs would not have to be incurred for each individual, but rather for each affected area. Of course if 1,000 people over a large area were affected the costs would be higher but for several dozen families in a single neighborhood with a nearby dump site these costs should cover the factual development of their case.

Thus a victims' compensation scheme should preserve state and federal common law to allow for recovery, where appropriate, beyond that provided by the compensation fund. The formula recommended by the § 301(e) Study Group is one which I feel would accomplish this result.

Should some of the liberated standards and presumptions available under a victims' compensation be included as new standards under common law? I am inclined to think not *if* the system will provide victims with the resources necessary to gather the relevant facts. Emerging doctrines of common law are, in some jurisdictions, beginning to recognize that scientific certainty is not a pre-requisite to recovery. New scientific techniques such as the work of research immunologists like Dr. Alan Levin of San Francisco conclusively establishing the presence of chemically induced immune system damage in blood samples of victims are making it possible for victims to meet their evidentiary burdens if they have the resources to make their case. However, if the resources to prove the case are not available, then the common law principles must be modified to shift the burden in order to preserve the opportunity for justice.

Finally, I do favor the principle that the federal law should clearly provide the opportunity to bring a toxic tort in federal court as a federal common law right of action. The potential for uniformity of development of common law principles and the stature of the federal judicial involvement in these issues if vital. It would be anamolous were Congress to properly recognize hazardous waste victims as a class deserving federal attention but deny them access to federal courts to redress wrongs not fully compensated by the fund.

Thank you for the opportunity to appear once again before the subcommittee. I will be pleased to answer any questions you may have.

Mr. LEVITAS. Thank you very much, Mr. Roisman.

Let me get to the question of scientific certainty on the one hand, and what you said, a lawyer's identification of a duck on the other hand.

I think you are—you do well to make such distinctions because there are two different disciplines involved and what scientists are seeking for their purpose may be somewhat different from what attorneys or courts or legislators are seeking on the other hand.

But let me get to the business end of it. Based on your experience in dealing with manufacturers of pesticides or other chemicals and marketing of them, is it your experience that these manufacturers demand scientific certainty as to all aspects of the efficacy or health effects of a product before it is actually marketed? Or are they willing to act upon information that they feel is of a high degree of probability as to either efficacy or health effects?

Mr. ROISMAN. I think it is clearly the latter, Mr. Chairman. In some way the whole dispute, if you will, if I could frame it in a legal perspective, between whether the victim is truly a victim or not, comes down to who has the burden of proof. If the presumption is that the person is a victim until they are proven not to be, then every victim will recover.

If the presumption is that the victim is not a victim until they can prove as a matter of scientific certainty that they are then essentially no victim will recover; or very, very few.

In the context of your question, pesticides, the premise of the industry applicant when they come forward with a drug or with a chemical for approval by the various Federal agencies is this is

OK unless you can prove that it is not. All the uncertainty is resolved in favor of saying it is all right.

Later down the line, if it turns out that we are wrong, you can always recall it. You can take it back. You can remove your approval.

That approach is not the approach taken down the line when someone says "I got it; I got the damage that you said would not occur." Then all of a sudden, the standard changes. Now it is required that you must come forward and prove that you are the one who is right.

So I think there is a double standard, if you will, that is applicable here.

Mr. LEVITAS. You mentioned about the 2,000 sites which EPA has already classified as imminent danger to public health. When you were at the Justice Department, did you have occasion to evaluate or take action or elect to take action with respect to any hazardous waste sites, or did that come in after you left office?

Mr. ROISMAN. No, my job was to do just that. At the time that my section was set up in the Justice Department, which was in October of 1979, the Environmental Protection Agency had already established a hazardous waste task force whose job it was to galvanize the regional offices of EPA to identify those hazardous waste sites in their jurisdiction, which presented imminent and substantial endangerments, to work those cases up, refer them to the Justice Department; and our job then was to take those that warranted legal action and take them to court.

I don't want to mislead you at all; we did not begin to make a serious dent in the 2,000 in the first year in which our section existed; we filed against 51 in that time.

Our first year ended just before the elections of 1980 and from that period, for the next 18 months, there was a total of, I think, 10 sites filed against, and, as of June 1981, until the end of the summer of 1982, there were no sites filed against by the EPA. There were no referrals to the department. I left the department in January 1982, primarily because there was no more work for me to do.

Mr. LEVITAS. Mr. Roisman, as an attorney, would you describe the cases that you dealt with as cases which were overall—not just from the legal point of view, but from the evidentiary point of view—rare, complex and difficult cases to bring? What I am getting at is, Mr. Roisman, based upon your position in the Justice Department, you had at your disposal a large amount of assistance—legal talent, research, experts, scientists, toxicologists, investigators—at your disposal.

Now, is it feasible or reasonable to accept that a private attorney handling such litigation would have the same resources at his disposal?

Mr. ROISMAN. No; not at all. If you will bear with me, let me just take you through the steps that the EPA and the Justice Department would go through to bring one of these suits, because I think it is illustrative of the problem.

To begin with, the Department and EPA then had—and still have—no authority to seek any compensation on behalf of victims. So, the whole side of the issue that goes to, did a particular person's illness get caused by a particular exposure, was not even part of our scientific investigation.

We did deal with the issue of risks because, depending on „the level of risk, you can determine what relief was appropriate.

But we never went that additional step and tried to link up an illness with a particular exposure.

Usually, the EPA would start with some kind of a paper notification; it might come from the State agency or a private citizen that said there is a dump somewhere out here, and the place would be identified.

EPA would send a team, usually made up of a couple individuals with scientific training and at least one person who had some special skills in doing analytical work or in gathering of samples. They would go out and take a look at the site.

If there was anything apparent offsite on nonprivate property, they would take a sample and take that back to a laboratory and run a scan on it, an MS/GC scan.

Those scans are costing the Government about $1,000 apiece in their own laboratories.

From that scan they would get information that would tell them whether, in fact, it appeared there was leakage coming off-site. If there were, then the next step would be either to seek permission or a court order to go on the site to take samples of what was in the dump, itself, and then to begin to drill monitoring wells around the site to try to trace where the contamination may have spread to, to figure out how much was coming offsite and what pathways it was on.

Each of the wells would cost several thousand dollars to drill; they had to be done in a particularly sound way, because the evidence gathered from the wells would be subject to challenge in court. The information that was gathered from the wells would be more samples, and each of those would go back through the same kind of a scan, although at this point you might be able to reduce the $1,000 cost because, instead of looking for 122 priority pollutants, you may only be looking for 10 or 15 that the first sample told you, or that your examination of the site told you.

After those investigations were completed, EPA technical people would evaluate the magnitude of the hazard. If they felt the hazard was serious enough that it warranted cleanup, they would bring in the Justice Department lawyers, and the EPA lawyers, and we would begin to apply the legal standards to the evidence available, and with that amount of information we would bring suit in Federal court.

The suit, itself, would then involve further investigations, and it would depend on the magnitude of the site and attitude of the defendant. A defendant who chose to fight quite hard, we would have to incur substantial additional expenses. Sometimes we would bring in the National Investigation Enforcement Center, which is located in Denver, and is EPA's creme de la creme of the technical resources, to do the ground water analysis.

Sometimes a full ground water study would have to be done because you have complicated aquifers.

We estimated that a minimum of $10,000 to $15,000 would have to be spent on any site to get enough information to even know whether we should bring a lawsuit or not, and the costs beyond that were really difficult to estimate.

But they could be quite high. All of those costs would be incurred by the Federal Government, and, I might add, that to the extent the Government brings enforcement actions with respect to particular sites, it provides a substantial amount of the information that any private citizen might need.

To the extent the Government does not exercise its enforcement authority, it not only fails to do its job, it makes it markedly more difficult for private citizens to get their recoveries as well.

Mr. LEVITAS. I have a number of other questions, but in the interest of having the other members participate, at this time I will recognize the gentleman from New York, Mr. Molinari.

Mr. MOLINARI. Thank you, Mr. Chairman.

Mr. Roisman, who are the Trial Lawyers for Public Justice?

Mr. ROISMAN. It is a public interest law firm that was established by trial lawyers to engage in litigation that would set important precedents in all areas of plaintiffs' trial law, and particularly cases that would not normally be handled by the private bar, either, because of the difficulty of the issues presented, the costs involved, or both.

There are about 350 trial lawyers who have contributed to the organization. We also receive some support from foundations.

The Trial Lawyers for Public Justice is a taxable professional corporation in the District of Columbia, and it is a project of the Citizens Legal Clinic, which is a tax-exempt organization founded in Tennessee, and has its principal offices in the District of Columbia.

Mr. MOLINARI. I take it that there are incidents of toxic poisoning, where plaintiffs may have a difficult time hiring a lawyer, which this group would look at as well?

Mr. ROISMAN. We have one case in which the trial lawyer who was retained called us and asked us if we would participate in the case with him because of the difficulty of the case, and so among our cases there is one that is of the type that we are discussing here today.

Mr. MOLINARI. If you would turn to page 6 of the testimony that you provided us with, at the top of the page you have a sentence that has a great deal of significance, and it is: "A properly taken and thoroughly analyzed well water sample will cost $1,000 to $3,000."

Would you define for us what you mean by "properly taken and thoroughly analyzed"?

Mr. ROISMAN. Yes; first of all, at the time the sample is taken, it is not as easy as simply going in, turning on the spigot in someone's home and taking a cup and filling it with water and taking it over to someone who has a lab.

If you are looking for volatile organics, you have to make sure, when you have taken the sample, that you seal the lid, or you lose the volatiles.

Second, the container must be clean, and frequently if you just go to a regular laboratory, what they clean their containers with may, in fact, be contaminants in terms of what we are concerned with, like benzene.

So, you want to be sure it is cleaned in a way that it is not self-contaminated.

On top of that, as a legal matter, you have to be sure the method by which the sample is taken does not subject it to damage in cross-examination at some subsequent time down the way.

So, you must make sure that you have run the faucet long enough that there is no danger that you are inadvertently trapping something in the water that should not be there; that perhaps someone has checked to be sure that the faucet is the right place to do the test. Maybe it should be done at the intake to the house so you don't inadvertently contaminate the sample with something in the pipes of the house, but having nothing to do with anything external to the house.

You have to do a chain of custody. You must be sure that the sample has been taken and under the control of an official who was able to testify that no one tampered with it, no one added anything to it from the moment it was taken until the moment it has been sampled and analyzed in the laboratory. So, that is the start-up side of it.

In the laboratory, itself, depending on the sample you have—it could be a water sample as we are discussing—you have to take a piece of that sample; it has to be subjected to the MS GC scans, which, as I mentioned before, the government was paying about $1,000 a scan. Private citizens are being quoted prices of $1,500 to $2,000, depending on where they are going.

A complete scan, thorough analysis, would mean that not knowing anything about the water except you want to know if there is anything in it, you would at least scan for the 122 priority pollutants that EPA has listed.

That is an expensive process, because the scanning mechanism basically produces a graph, and when you look at the graph, you are looking for certain peaks which correspond to what that machine has predetermined represents particular chemicals.

So, for 122, you are looking for different peaks. There is a fair amount of time spent in the lab checking the peaks found from the sample against the peaks established for that particular machine for the chemicals. I might add the lab must exercise a certain amount of control over the samples so that if someone wants to resample the same sample to the extent that it can be saved—volatiles are much more difficult than others—it is available to be resampled by someone.

Mr. MOLINARI. So if a citizen or group of citizens that live near a dump, suspected that there was a problem with water contamination, a sample could be taken with due care that all the custody and control techniques were proper. What would it cost to determine what is in that water?

Mr. ROISMAN. What I have suggested here is $1,000 to $3,000. It depends. Sometimes you get a lab, if it is in a university that may do it for less, or a person taking the sample may have access to an equipment lab where they don't have to pay as much. What I advise people to do is to try to find a less thorough scan that will just give them a quick look at whether or not there are organics, for instance, or whether or not there is evidence of some kind of contamination in the water.

Those scans can run anywhere from $60 to $250. They don't tell you what is in there; they tell you whether there is a likelihood that there is something in there, and then you can make the larger investment, or maybe if you are fortunate the existence of that will be enough to persuade either a State or Federal agency to run the remaining test for you.

They would use that—I must add, a fair amount of press coverage—to awaken the bureaucrats to the need to do the sample. Often, when you send the sample from your home to the State lab, they will come back and tell you your water is clean, which means they did not find any fecal coliform in it. It is potable. It does not mean that it does not have toxic chemicals in it.

Mr. MOLINARI. This is a very serious point that we don't seem to see emphasized very much throughout the country. That is, the threat to the individual who uses well water, even in New York City, where we don't rely on ground water for drinking water supplies except during drought periods when thousands of wells may be put into use. In many, many areas we have toxic contamination, and I have been very concerned about the fact that people will take a sampling to a laboratory which finds it negative for bacteria and viruses, but no one tests for toxics. Obviously, people think it is safe. I have serious concerns as to the potential for an outbreak of illness.

We have, in my district, a 6-year-old girl dying from a condition we suspect might have been caused by irrigation of a golf course across the street from her home with seriously contaminated water.

When you served with Justice, would you have characterized the emphasis of the Department during that period of time as one that would prefer to litigate or to settle?

We have heard that bandied back and forth during the current administration. What was your experience during your tenure?

Mr. ROISMAN. I was there for 1 year under the current administration and for about 1½ years under the previous administration. Under the previous administration the position which I frequently stated was that the Justice Department and the Environmental Protection Agency were anxious to reach settlements in every possible case we could reach them in, and the only way we could be assured that we could reach them—and reach them on terms acceptable to our goals of getting proper cleanup of the sites—was to litigate.

We made crystal clear to the prospective defendants that we would not tolerate the failure to negotiate quickly and completely. When we did not get settlements, we sued. When we gave drop-dead dates, as that term was used—not in our administration, but in the current one—we did not fail to meet those dates, and we did not give them lightly. When we took a case to a defendant before filing suit, which we did frequently, we already had a complaint; we had it approved at the Assistant Attorney General level in the Lands Division, which meant that it was approved for filing. We usually had it already at the U.S. attorney's office waiting to be filed; we had its approval from the EPA, from their Enforcement Director; and then we would write a letter to the defendant, and we would say within 10 days we intend to file suit against you, but if you wish to talk about resolving this matter, we will be happy to do it.

Within those 10 days, it would be obvious whether they were prepared to reach reasonable terms with us. If so, we would extend it. Once, we extended it as long as 30 days and reached a settlement with the Syntex Agribusiness Co. in Missouri. I mention that both because I think that it was an example of how the two parties came together, and also because it is the Syntex Agribusiness site from which the dioxin that contaminated the rest of Missouri originated. The settlement we dealt with was on one place where the dioxin was disposed of.

Mr. **Molinari**. Let me interrupt, if I may, because we are limited in time on the first go-around.

We have heard conflicting reports during the subcommittee's investigation of the EPA and the Superfund. Rita Lavelle was characterized as one who favored settlements. Yet when she testified before us, she was highly critical of Mr. Perry.

Mr. **Levitas**. Who she claimed, and others claimed, had a total emphasis on sue, sue, sue, and she felt that oftentimes that would interfere with the ability of the Government to settle cases where they were less than perfect.

Indeed, we had a memorandum that I had obtained, which was signed by—prepared by—Mr. Yamada. Are you familiar with him?

Mr. **Roisman**. I know Mr. Yamada.

Mr. **Molinari**. And Mr. Yamada, who is still in EPA's employ, sent a letter to all 10 regions of EPA, holding a gun to their head, demanding that they refer cases to headquarters for litigation and, in fact, went on to suggest by a graph that based on the referrals to headquarters, the allocation of full-time employees to each of the regions would be determined. I come from region 2, and they had, I think, 27 full-time employees; based on the slow referral rate they were going to get 12.

So I am having difficulty in my mind trying to equate what you are saying, what Rita Lavelle was saying, and what Mr. Yamada was saying, and, in fact, the memorandum.

Mr. **Roisman**. Perhaps the best I can do is sum up this way: Starting in January 1981, with the end of the Carter administration at EPA, we basically entered a period of the Amateur Hour. The people who were brought to the EPA to replace the people who had been there before knew nothing about what they were doing.

There is one consistent explanation that I think explains the Agency's actions. It is that they were totally incompetent and did not know what they were doing. Ms. Lavelle thought she wanted to do settlements.

Mr. Perry wanted to do litigation. You can't do one or the other. One is a carrot; the other is the stick. You have to put them together if you want the donkey to move ahead. You have to do both.

I think the EPA, when I helped in the hazardous waste section, was the kind of EPA capable of understanding the subtleties that you had to reach settlements in the atmosphere in which litigation was a known reality and not as it was in this administration, a total nonreality for over a year after it took office. There was no way to negotiate a good settlement.

So, while Mrs. Lavelle wanted to have a good settlement, perhaps, she had no chance of getting it in a conference room when the people on the other side knew that they could get a meeting with the Deputy Administrator, with the Administrator—maybe at the White House, for all I know—and get new conditions.

So, you never had an effective program going. That, I think, is the source of the problem. It is difficult to try to explain away all of the inconsistences in that administration, because I think that they are not explainable except if you start with the premise that most of those people did not know what they were doing.

Mr. MOLINARI. Would you advocate a system where, as soon as Justice had adequate facts, it would institute a suit and at the same time pursue negotiated settlement?

Mr. ROISMAN. The Justice Department position—the first major case that I had, that issue arose, and we had a defendant that said to us, please negotiate with us for 6 months; don't sue us; and we went to the then Deputy Attorney General of the United States, and we asked him his advice. He said the Justice Department does not condone the practice of forestalling litigation for an indefinite period of time that is ready to be filed in anticipation of settlement discussions.

We file the suit, and if there is a settlement discussion which will go on, it will go on after the suit is filed.

Mr. MOLINARI. Isn't there a very distinct possibility that, in the case of some large corporations who value their reputations, they would have more reason to want to settle prior to suit; that once the suit is started, and their name has been exposed, they might as well, if they feel they have a decent case, fight you all the way, and you have lost your opportunity to negotiate a settlement?

Mr. ROISMAN. That is why we normally send a letter and offer a 10-day period of time during which time we could evaluate——

Mr. MOLINARI. Is 6 months an unreasonable period of time?

Mr. ROISMAN. It was in this case. By the way, the case did settle.

Mr. MOLINARI. In dealing with a major corporation who you suspect does not want to have its dirty linen aired, and it says it would like to have 6 months to try to effectuate a settlement, as a general rule——

Mr. ROISMAN. First of all, you must understand that the government's case has probably been 6 months in the development by that time, from the time that that first investigator went out there and began to take samples.

Usually, a company who genuinely wants to settle will have made telephone calls already. We don't have to initiate the settlement discussions. If we have gone through that process and it is already 6 months down the road, we have not heard from them, we, as a courtesy, send them a letter and say, look, if you want to talk, we will give you 10 days. If in that 10 days we felt they genuinely wanted to settle, and there was good reason why we could not get the settlement completed in the 10 days, as there was in the Syntex case I mentioned to you, we would postpone. We did that. We waited 30 days. The night the settlement was reached, the team of negotiators stayed up all night, because the next day we had said we were going to file this suit.

Mr. MOLINARI. Interesting.

Mr. ROISMAN. I think it is important to remember that the two parties to this don't have exactly the same goal. If you don't keep their feet to the fire, you are not as likely to get a successful settlement at the level that you need in order to get adequate cleanup.

Mr. MOLINARI. I yield to the gentleman from Florida.

Mr. SHAW. What you are saying is that during the investigation period, a certain amount of negotiations have been ongoing?

Mr. ROISMAN. Sometimes. In the investigation period, when I was there, the Government did not make any overtures. We did not go to the company and say, "Hey, we are investigating your site; would you like to talk about settlement?"

Frankly, we did not know whether—we did not know whether we had a case and whether there was anything to settle. But the company usually knows a lot more than the Government does about what the situation is.

Sometimes the company will come to us in that time and say, let's start talking, and we would talk and investigate.

Mr. SHAW. I am a little confused, then. Are you saying that an adversarial relationship is established immediately upon the start of the investigation rather than the parties working toward an end result to get the problem cleaned up?

Mr. ROISMAN. No; adversarial relationship is not my term. What I would say happens is that the Government starts the process of investigating the site. At that time, the company can come in and begin to cooperate with the Government and say, "Look, we want to get the same answers you do, and we want to do the right thing based upon those answers," and we say, "Fine, let's cooperate." We might take split samples; we might go to certain places, open up the records and see what wastes have been dumped in the site, so we don't have to spend time sampling the site.

Mr. SHAW. Was that the usual situation, or was that the exceptional situation?

Mr. ROISMAN. That was—certainly in my tenure that would have been considered the exceptional situation.

What we found was that the company's interest in settlement usually began to rise first after we had enough information to believe that a case should be brought, and, second, after we had been in existence for a number of months and they realized we really were going to bring the cases.

Mr. SHAW. Don't you think that a little evolution may have occurred over the last few years as the toxic wastes problem has become readily recognized as being as severe as it is, that maybe the atmosphere may have changed to where companies, responsible companies, are much more willing to expedite a solution to the situation rather than look down a gun barrel?

Mr. ROISMAN. I hope so. But our premise was, and if the authority were mine to exercise again, my premise would still be that you must pursue settlement and litigation on parallel tracks, not on the same track.

One does not wait for the other. You must continue to prepare for litigation on the premise that if the settlement falls down, you are ready to go.

We were dealing with sites we had already determined were imminent and substantial endangerments. We did not feel it would be responsible to delay.

Let me just explain in my last months in the hazardous waste section, I proposed, but had no success in getting approved, an increase in the size of my section to set up within it a group of lawyers who would do nothing but negotiate. I believe it is difficult for the same lawyer to litigate and negotiate both. I think it takes a different kind of lawyer to do it, and the way you walk into the door of the prospective defendant alters, and that is, in the most classic sense of what we see on television; you know, a white hat and black hat. You need the nice guy that says I don't want to turn this other guy loose on you; he is trying to get into court; he likes to litigate. I want to negotiate and settle.

I think that that would have been an effective way to address your concern, which is that you do not want to litigate unnecessarily, and you don't want to negotiate at a level where you do not get what you need.

So that you can accommodate both in that way. For us, I think it was working.

Let me premise all that; that whole situation only existed for about a year, from October 1979 to the end of 1980. After that, it was entirely different. My section was abolished in June 1981, and the flow of cases and cooperation between the department and the EPA essentially ended. So, we don't have a substantial amount of experience with it, but it was working, I think.

Mr. SHAW. I did not mean to take up that much time.

Mr. MOLINARI. That is OK.

What I would like to do, if I could, is ask you to put your present hat on now and take us through a scenario as to what happens when you, as an attorney, have clients who come to you and say they have been suffering, they and their family, from a variety of symptoms which are readily recognizable as being the result of exposure to a toxic dump site?

How do you evaluate whether you are going to take the case? What factors go into it? Let me ask you this as a preliminary question: You have handled a number of those, I assume?

Mr. ROISMAN. We have only one in the office now. We have one other which is a substantial one under investigation, and we have consulted on some.

Mr. MOLINARI. All right.

How would you evaluate whether you are going to take a case?

Mr. ROISMAN. The first thing we do is see to what extent the Government has already done some investigation. If somebody walks in and says, I live near a certain site; the Government brought a suit against it, and we would get, either by cooperation with the Government or under the Freedom of Information Act, or from the court files, whatever evidence had been gathered to try to show what the hazard was at the dump, where it went, and all the rest.

Second, we would attempt to determine how the person was exposed. Did they have a pathway of exposure? If the dump caused only underground leakage and this couple lived upgradient from the site, it would have been difficult to see how they could have been exposed that way.

Then we would attempt to get the help of technical experts who could evaluate with us whatever information was readily available. If it appears that they were downgradient from the site, but we could not establish whether their own drinking water was contaminated, we may have to go out and get a sample, if the resources were available to do that, and find out if there was contamination of the water supply, and if it was of the same kind of chemicals in the dump.

You could have the contamination, and it could have no connection to the dump site.

We would have to check with the patient's doctor to see whether or not the doctor had found any illnesses that seemed to have a linkage to toxic chemicals. The family doctor usually does not think in terms of linkages to toxic chemicals, but he can at least identify the illnesses. Some illnesses are related to certain chemicals.

Some are so closely related that the very presence of the illness is almost a guarantee that the exposure must have been there. But in a more common case it is a class of illnesses such as kidney failure.

Kidney illnesses are related because that is where the body does a lot of its washing and cleaning, and thus if you have taken in a toxic chemical, you are likely to find something in the kidney or in the liver.

So we would do that.

Then we would see if we could find in that State law that was appropriate for recovery. First of all, there is a statute of limitations problem; second, in some States the toxic torts have a much less chance of success than in other States.

So, we would have to make a legal evaluation. The cases are driven by the facts, though, and we operate on the premise—true for good trial lawyers—good facts make good law. If you can't make the case, the plaintiff has no case, you can't win on the law if you are the plaintiff. You can only win on the law if you are the defendant.

So, you have to get the facts.

Mr. MOLINARI. I would like to ask one last question and defer to my colleagues.

From the plaintiff's lawyer's position, isn't it more than good facts make good law? Doesn't it also take good injury, good in the sense that it takes a very substantial injury in order for you to consider handling a case, because these cases, as I understand, are handled on a contingent fee basis?

Mr. ROISMAN. That is correct.

Mr. MOLINARI. Unless the injuries are severe, the investment of time on your part, or your firm's part, is so substantial and the amount of expenses in the investigative phase, laboratory work, and all the rest, is so large that the case may not be taken on. We have been told in this committee that there are few qualified medical experts you can use in this country to put on your case.

What I am driving at is that I don't think the vast majority of those suffering in this country fall into that—hopefully don't fall into that—category where there are severe injuries, severe from the standpoint where we are talking about judgments or settlements that might be in the million-dollar range.

But they have suffered; they have suffered substantially. They have had many medical problems, a great deal of doctor and hospital bills, and yet they don't fit into that category where an individual case would merit a lawyer taking the matter on.

Mr. ROISMAN. I think that is a fair statement.

Mr. MOLINARI. I see this as one of the biggest problems we have to face. By and large, the masses out there who are being injured do not have adequate remedies even under the best of circumstances regardless of what State you are talking about, and whatever body of statutes are in that State. Very simply you just have the difficulty of proving a case which is so complex that you cannot afford to take those cases. That is what we have to address, I think. The masses out there don't have a legal remedy, as I see it.

I just wanted to make that observation. I would yield.

Mr. LEVITAS. Dr. Rowland?

Mr. ROWLAND. Thank you, Mr. Chairman.

Mr. Roisman, you used an anecdote to illustrate the difference between the way a lawyer looked at this problem and the way the scientist looked at the problem.

Mr. ROISMAN. Some scientists, yes.

Mr. ROWLAND. Yes. You said that if a duck walked in and the lawyer would say it walks like a duck and acts like a duck, and quacks like a duck, so it is a duck. The scientist would look at it and before he made the decision would dissect it and look at the inside of it.

Say that a group of people in this room decided that that duck was not a duck. Do you suppose they would have any difficulty in getting an attorney to represent them in proving that that duck was not a duck?

Mr. ROISMAN. Well, I guess, to put it in crassest terms, it would depend on whether they could pay the attorney.

Mr. ROWLAND. That is the point for me there. I appreciate that. But they would if they could afford the attorney, be able to get one that would prove that that duck was not a duck if he could?

Mr. ROISMAN. I think it is a fair statement, and, as an attorney, I don't mind fessing up to it; that lawyers, regardless of how they do it, are hired guns. Some of us draw our guns for more selective clientele than others, but that is what we are. We are paid to provide services, and usually—I have been asked the question; I can't tell you how many times—can I sue so-and-so, and then I hear some story or something, and the short answer is sure, you can sue; you can't win.

I guess there are lawyers—I can't think of any plaintiff's lawyers that would take your hypothetical case because most plaintiff's lawyers are only paid if they are successful.

So, they are compelled to evaluate the merits of the case and whether it could succeed. But defendant's lawyers are different. I bring suits all the time that appear to be defended by lawyers proving that ducks are not ducks.

Mr. ROWLAND. Your anecdote established—your point was that lawyers are sort of together and scientists are really not. That was what I got from your story.

Mr. ROISMAN. I am sorry. What I really meant to suggest to you, and I apologize if I misspoke, is that the legal system as it evaluates the question, evaluates it differently than the scientific system does. Each has a good reason for doing what they do. But we are looking at a legal system approach to a problem, and I think it is important to put the scientific solution into context.

I am not an opponent of the scientific solutions. I don't think they should dominate the question as between A and B, who should recover, because if they do, the one who is entitled to recover may not learn they can recover until it is too late to do them any good.

Mr. ROWLAND. Do you feel there is enough evidence now, based on your present knowledge, to say that toxic chemicals are posing definitely a significant hazard to many people in this country?

Mr. ROISMAN. To me, yes. But I am speaking not as a scientist, but as a lawyer. I have talked with scientists; they tell me that. I believe them; I consider them credible, and I believe that.

Mr. ROWLAND. We heard some conflicting testimony here from two different people during our last meeting about whether or not there is enough proof at this time. Would you think that there is considerable confusion now among the scientific community about whether or not it is a serious problem at this time?

Mr. ROISMAN. I think there are scientists who say that it is not, and there are those who say it is. I don't know whether it is confusion. We are the ones who might be confused by it. I think each body of scientists feels confident they are right.

Mr. ROWLAND. Do you know now if there have been many cases that have been settled by people who are seeking compensation for injuries from toxic chemicals in the country?

Mr. ROISMAN. I am not aware of very many, but I don't have a good grasp on the total of all those in the country.

Mr. ROWLAND. Thank you very much.

Mr. LEVITAS. Thank you, Dr. Rowland.

Mr. Shaw?

Mr. SHAW. Thank you, Mr. Chairman.

I got my main questioning done on Mr. Molinari's time, but I have one more.

You used the term in your direct examination, "scientific certainty." Would you define that term for us, which I assume is the same as medical certainty?

Distinguish it, if it is distinguishable, from the preponderance of evidence.

Mr. ROISMAN. It is easier for me to define it in terms of an example. If you start with a toxic chemical, and you run a laboratory experiment with a set of genetically identical mice, half get it, half don't; you then look at the mice a year down the way, and you see what has happened to those who got the toxic chemical, and you find a statistically relevant number of the exposed mice got some particular illness, and you are then able to say that this chemical appears to cause this illness in these mice. I guess if the tests are run properly, you probably—and if you had a statistically large enough sample to work with—you can say as a matter of scientific certainty that that level of that chemical causes that illness in mice.

Now, when you start to ask the question, well, does it cause that illness in humans at that level or lower level, or higher level, you have gone outside of what scientific certainty demands and a scientist, as I understand, would say in that case, until we have had a comparable human exposure to the chemical at the levels in question and had a statistically relevant sample of exposed and unexposed, we cannot say, as a matter of scientific certainty, that it is true.

That is how I understand that.

Preponderance of the evidence is a legal concept that says there must be at least 51 percent of the evidence which is reliable and credible, which the decider believes favors the particular proposition.

Was the light red or green? You have a witness that stands up and says, I saw it; I was looking right at it, and it is red. Another witness gets up and said I saw it; I was looking right at it, and it was green.

We have no more evidence and both witnesses are equally credible; then we don't have a preponderance of the evidence, because we have half the evidence saying it is red, half saying it is green.

Mr. **Shaw**. Can the trier of fact in a court of law make his determination in favor of the plaintiff based upon the fact that the preponderance of evidence indicates that the rats did die or did contract an illness because of exposure to the toxic waste?

Mr. **Roisman**. You mean, is the jury entitled to make the inference?

Mr. **Shaw**. Yes.

Mr. **Roisman**. In the court system the court might, in the first instance, have to pass on the issue of whether or not that question could go to the jury. Is there enough evidence? The defendant, for instance, might move in our hypothetical to say that it is not reliable and credible evidence; that animals exposed to the chemical in question got sick, to prove whether humans exposed to it had their sickness caused by it.

So you would have a court passing first on the legal question. Some courts, I think, would say, yes, we will let that issue go to the jury. Let them decide, after hearing the other experts testify regarding the reliability of animal studies for predicting what happens to humans.

In other courts they would say, no, we will not let that go to the jury. It is not reliable enough to take it to the jury.

So, in the case where the court allows it to go to the jury, then, yes, a jury, if it decided to also believe the testimony of other experts who would make the linkages between the exposures to the animals, the evidence from that and the exposures to the humans, and what relevance that may have with relevance to the exposures to humans, you would have a jury that says, yes, that is enough evidence for recovery.

In some cases the same court, with a different jury, may get a different result. It will depend on the quality of evidence on both sides. The defendant has experts testifying on the unreliabilities.

Mr. **Shaw**. Do you see an evolution toward allowing this to go to the trier of fact rather than directing the—

Mr. **Roisman**. I would say the trend is more toward allowing it to go to the trier of fact. That is, in part, I think, because so much of what the Federal Government and State governments do in setting regulatory standards, uses the animal study data, the Delaney amendment, is based on the premise that what happens in animals has a reasonable bearing on what happens in humans. I think you have a good chance of getting to the jury.

My own sense is that you have a far better chance in front of a jury if the question you are asking is, did the plaintiff's exposure to the chemical that we know causes this problem in rats subject them to a significant risk of increased illness which entitles them to recover?

There is a better chance that that question will be answered affirmatively than did the particular illness that they now have get caused by the exposure to that chemical which has been shown to cause that kind of illness in rats.

Mr. **Shaw**. Do you see a statutory need in that area?

Mr. **Roisman**. I think in terms of providing for the recoveries that we have been talking about at the objective level, medical expenses, lost earnings, lost property values, yes, I believe that a statute is valuable and essential to make sure that that level of recovery on which we can be certain of the damages is recovered by those people who were in that category.

But I feel that at the second level, when you talk about pain and suffering, and when you talk about punitive damages, that it is more appropriate because we are dealing with a more intangible damage, that we should allow the common law to evolve on its own in the State court system.

Mr. **Shaw**. Thank you, Mr. Chairman.

Mr. **Rowland** [presiding]. Mr. Albosta.

Mr. **Albosta**. Couple of questions.

Have you represented any clients that were successful in their claims against companies for toxic contamination?

Mr. **Roisman**. No.

Mr. **Albosta**. In your opinion then do companies tend to use confusion as part of each one of their cases?

Mr. **Roisman**. Confusion?

Mr. **Albosta**. Confusion.

Mr. **Roisman**. They present the opposite point of view in their cases. None of my cases have gone to conclusion. The corollary of your first question was not that I have had any clients that have lost either. So far in the one case I am pursuing the defendant's position in the case was to deny that they were responsible even for the contamination of water and to try to compel us to prove that that had happened before discovery had been taken in the case.

So what I am experiencing is really I guess for lack of a better term, stonewalling.

Mr. **Albosta**. Let me clear my question up a little bit. Two scientists sitting side by side both with about the same experience could come up with different conclusions to a case.

Mr. **Roisman**. Right.

Mr. **Albosta**. In many cases those—the company's point of view from the scientist is that it is a more neutral position, if you will, toward any toxic substance having anything to do with health effects. Whereas the other scientist may take the view that of caution and says well, it is possible that this could do this, this or this even though the manuals and journals don't contain that information that says that.

Doesn't that create confusion? I suppose from a legal point of view a company would want to do that. How do you win then? How do you—how can a person contaminated ever get a good case other than having an arm fall off, a sore somewhere on his body sticking out or a tumor or something that is identifiable. How can they ever get a case without that?

Mr. **Roisman**. To begin with, it is quite common that plaintiffs recover in cases where defendants put on witnesses that contradict the plaintiff's witnesses. It is a matter for the jury or if you don't have a jury, for the judge to decide which witnesses' testimony is most credible, most believable, which states the facts.

On top of that, it is more difficult to recover where the nature of the injury that the plaintiff has suffered is less visible than what you have just described. But it is also possible to take the jury inside the human body and you can show the damage to a human cell as dramatically as you can show damage to the arm.

If the witness—if the evidence is there for the witness to be able to so testify I think that the plaintiff has a significant possibility of recovering in that case. If it is not there, as I said before, a plaintiff cannot win without the facts. If no scientist of any credibility is prepared to get up and testify, yes, I have seen the damage from this toxic chemical in this human body and it does this and this and this, then the plaintiff doesn't have a case. They cannot prevail. That is an important difference between plaintiffs and defendants.

Defendants can prevail on legal issues or on the failure of the plaintiff to be able to present their case. But the plaintiff can't prevail if they can't present their case.

Mr. **Albosta**. A defendant would have to show a liver that was damaged then, you say to go inside the human body, the scientist would then show the jury or the court a liver?

Mr. **Roisman**. Not necessarily.

Mr. **Albosta**. A kidney?

Mr. **Roisman**. He might have a blood sample, tissue sample. I believe Dr. Carnow—I don't know whether he testified about this but he has done work in the immune system where you are able to take blood samples from humans and examine the immune system and see whether we have a damaged immune system, one that does not respond to the variety of attacks that come from outside the body as well as it should.

And make conclusions regarding what caused that system to be damaged and what are the consequences of that damage, what might happen to the patient even if nothing very serious has yet happened.

Mr. **Albosta**. From your point of view, legally, isn't it very, very difficult to take a case of toxic poisoning that one person may have and another one which would simply not show any poisoning from the same exposure and take that to court and win? The question better put would be, isn't there a difference in people where one will withstand the exposure to toxics better and another will not?

Mr. **Roisman**. True.

Mr. **Albosta**. Isn't that very difficult in court to show that there is a cause from that exposure when you have a person that is perfectly healthy and another one that says my cancer was caused by the exposure, same exposure, yet nothing happens to the other guy?

Mr. **Roisman**. We have medical people who say that that is not difficult. If you start with the premise that each human is different then it follows one will be affected differently. One basic principle of the law is you take the plaintiff as you find him. If the person has as a result of a prior accident some propensity to damage and then they get damaged by something that would not cause any of the rest of us to be damaged, the person who damages them is responsible for that even though that person happened to have this much higher propensity for being damaged. That would be equally true here.

Now, obviously the person who has not been harmed at all will not recover. He shouldn't. But the one plaintiff is not substantially damaged by the presence of some one who has not been damaged if there is medical testimony to link the plaintiff to the toxic exposure.

Mr. **Albosta**. What is your opinion about what Congress can do to improve on the laws? I don't think I should say to make it easier. What I would like to say is to make it so that people that are damaged by some toxic exposures can recover somehow. What exactly in your opinion should be done, seeing you worked in the Justice Department, and in the environmental area.

Mr. **Roisman**. There are several things. In terms of existing legislation I think the Congress should continue to put pressure on the Government to use its existing authorities to investigate the hazardous waste problems of the country, to settle or litigate as to those, to complete the work that the Superfund law imposed upon the Government which includes setting up a health registry for the Nation that would give us a lot of the answers.

The Government had to be sued about that. They eventually settled that suit but are still not committing the resources to it that they should be committing and it is all Superfund resources, so it is off-budget money, it is not budget money so to speak.

The Government should be doing the onsite investigations that would give us a better idea as to where the hazardous waste dangers are and where the victims are; if there are any, they are most likely to be physically located there.

I think victim compensation legislation should also exist which would provide a recovery for the objective kinds of damages that we have talked about here today, the medical, the out-of-pocket medical costs, the lost wages, property damages.

And that that system should include in it a mechanism by which a party who comes forward and establishes a minimum level of evidence such as I consumed the toxic substance, there is a site near my home that has that toxic substance in it, it is in the ground water, it is in my well, at least that much, ought to then entitle that person to some financial help—if the Government hasn't done its own work on the site to complete the evidentiary basis to be able to then establish are they really a victim and entitled to recover.

Then the Congress should allow the private tort system to continue with respect to other kinds of intangible damages and allow the, if you will, the marketplace to sort out which of those plaintiffs are entitled to go on and pursue punitive damages, pain and suffering, losses and other things that are in the intangible area and not either preempt that law or attempt to superimpose upon it a new set of standards.

If the Congress could compel the executive to carry out the authority that it imposed on the executive when it passed the Superfund law, much of my concern about the costs for victims' compensation legislation in terms of being able to give the victim the resources to prove their case, would be unnecessary. I think you have put into motion what could have been a mechanism to give a lot of the factual answers to these questions and that would then have enabled people to come forward without these enormous financial burdens imposed on them personally to prove their case.

Mr. ALBOSTA. Do we relieve the producer of the toxic substance of responsibility in your opinion when we reach a settlement out of court and then sign papers to alleviate them of any further damages?

Mr. ROISMAN. Yes.

Mr. ALBOSTA. Does that happen?

Mr. ROISMAN. What happens is that there will be a Government suit in which the Government absolves the defendant of any further liability to the Government. Now obviously they cannot absolve them of liability to private parties unless the private parties were party to the suit. When the Government does it what it does is say we the Government will accept the risk of the unknown. In settlements we have reached when I was at Justice, we would not sign such a settlement. We would require the settlement terms impose the risk of the unknown on the defendant.

Mr. ALBOSTA. Are they signing those settlements now?

Mr. ROISMAN. Not to my knowledge. I have not looked at any in the last couple months.

Mr. ALBOSTA. Thank you, Mr. Chairman.

Mr. LEVITAS [presiding]. Thank you, Mr. Albosta.

I have just one last question and I will recognize the rest of the members.

Does it make any difference, if you know, if one develops a health problem from exposure to a specific hazardous chemical as opposed to exposure to a hazardous waste site in which that chemical is contained. Specifically, what calls this to mind, I heard last week that I think it was EPA announced that they now have conclusive evidence or proof, whatever, that dioxin is a very poisonous carcinogen, and whatever. I thought it—I was laboring under the assumption it was for a long time but anyhow they came out with that report.

It is also my understanding that very small quantities of dioxin can create health problems in an individual. Does it make any difference whether that exposure is a result for example of spraying of dioxin-containing materials on asphalt or incinerating PCB's at appropriate temperatures in apartment houses or hospitals or direct exposure or in proximity to a hazardous waste site that contains the dioxin?

Mr. ROISMAN. I am not confident that I can answer the question. I think I understand where the answer lies. One of it has to do with the form in which you were exposed to the dioxin can affect you differently, whether it is on your skin or whatever. I don't believe you get it in through the skin although chloracne is a phenomenon with it. I know if you inhale it can affect you differently.

Also in any of those different media it may be mixed with something else which could cause a synergistic effect which might mean that combinations of dioxin and one other chemical is worse than each of those chemicals separately.

So that there are factors but I don't know the answer specifically to the question of which one of those places makes it worse or which one makes it better. I don't know whether the scientific community has an opinion on that either.

Mr. LEVITAS. Thank you.

Mr. Molinari.

Mr. MOLINARI. On that question, I think I recall information to the contrary. I think you can absorb dioxin through the skin. That is one of the points of entry. I think that is what makes it particularly dangerous.

I would like to get an answer on victims' compensation. You do outline in your testimony a suggestion. I would like to address that briefly.

Your suggestion is that you establish a low threshold standard for the victim to meet. Once that standard is met then the victim is entitled to a fund-compensated scientific and medical investigation.

Mr. ROISMAN. Yes.

Mr. MOLINARI. Earlier in your testimony you indicate that for a good and proper medical and scientific workup lawyers taking toxic tort cases are anticipating a minimum of $100,000 to $200,000 in costs just in gathering the scientific and medical information required to prove a claim.

When I applied that cost to my own State, because of the familiarity I have with the figures in my State—I think New York has 22 Superfund sites, we have over 1,000 what they call "mini-Superfund sites" being investigated at the present time, and we are obviously talking about very large numbers of individuals.

Perhaps thousands, that have some health problems attributable to this exposure. So when I start to multiply the figures out I come up with a phenomenal amount of money nationwide in order just to get past point one.

Am I correct in that assumption or am I missing something?

Mr. ROISMAN. No, no, only in this regard, that if you have—assume that at each of the 22 sites you have 100 potential victims, 2,200 people. The investigation that is good for one victim will be good for all at the site. So that it is easier probably to see those numbers in terms of per site rather than per individual necessarily.

Second, the revolving fund nature of this proposal means that over time the fund gets its money back as the victim is able to recover, they of course would recover their costs and they would be expected to pay those back into the fund so that the fund—I am talking now about those victims who go—using the section 301(e) study language—from the first tier to the second tier. In the second tier the person who recovers would have to pay back to the compensation fund their pro rata share of these costs.

So there is the opportunity for some revolving fund. But your premise that it is an expensive effort to make the evidence available and draw the distinction between the true victim and the non-true victim is correct, it is an expensive business.

Mr. MOLINARI. There is no question about that.

Mr. ROISMAN. I don't think it is out of proportion to the need but it is there.

Mr. MOLINARI. There is no question about the fact that it is expensive. I think most of us are prepared to move towards providing some type of relief. But there is one thing that I think either you are missing or I am missing. When you talk about the revolving fund, my experience with most sites—I don't know what the percentage would be—is that most of them are sites that may have been operated by shell corporations, people who don't have any money. They hit and run, and the chances of recovery would be rather slim if you are going after the responsible parties.

So I am puzzled as to how that revolving fund will replenish itself.

Mr. ROISMAN. This same issue arises under Superfund itself.

Mr. MOLINARI. Yes indeed.

Mr. ROISMAN. It is my sense that at the time the fund was passed that that law was designed to use the enforcement mechanism to deal with the site where the responsible party was located, either in litigation or settlement, and that the bulk of the funds in the fund were to be used for the sites where there was no responsible party available for the true orphan site as opposed to an abandoned site situation.

I don't know—I am not as confident on this—that of the total number of sites there are more orphans than there are abandoned or active ones. But it is possible that the fund cannot, certainly it will not revolve to 100 percent, there will be diminution over time. We have not had enough experience with the Superfund to get a sense of that because the Government has not pursued much, if any, recovery suits yet.

But let me just go back to the other point and be clear on this. I mentioned this to Mr. Albosta, also, and that is that the current law, the current Superfund law has in it in section 104(i), that the public health service is to establish an agency for toxic substances and disease registry.

Then in sections 104(e), 104(b), and 104(a), the EPA through the President is given the responsibility to investigate these sites. We have already made the commitment as a country through the Superfund to gather much of this raw data. My feeling that we need to make sure that the victims' compensation scheme provides for the resources to do the medical and scientific investigations is based in part upon my cynicism about the present administration's willingness to use Superfund for what it was intended to be used for, and also that there will be some instances in which a site is causing a problem but for one reason or another has not gotten priority enough to get the Superfund money for it.

But it may be that a lot of the money we are talking about has already been anticipated—maybe the fund itself, the $1.6 billion Superfund—isn't nearly large enough to accommodate that because there wasn't enough momentum at the time that the bill got passed to put in the larger sums of money.

But those costs are going to have to be incurred and many of them, not all of them but many will have to be incurred by the Government if it is going to move against the site to be sure it is cleaned up so the number of victims doesn't continue to increase.

There is no benefit here to anyone to be able to say, let's keep it open and operating so that in 20 years we will have another group of victims who can bring another multiple dollar lawsuit. The Government should be shutting down the source as quickly as possible.

Mr. **Molinari**. That leads me to one important question and I think based on your own background you can answer it. My feeling is that regardless of all we have done here at the congressional level, and the inordinate sums of money we are talking about, the one thing I do not see is enough discussion on prevention. We hear of examples like Times Beach, where for less than $100,000 we could have legally disposed of the dioxin. Yet for only one buyout, and it is only one portion of the area contaminated in Missouri, the Federal cost is $33 million.

The emphasis seems to be on going after a condition after it is discovered and then trying to cope with the problem under very difficult circumstances. It seems to me that we should have much greater emphasis on detection, prevention and enforcement so that we don't wind up with these tremendously costly and difficult problems. I don't see it happening. I just wonder what your observation is along those lines?

Mr. **Roisman**. I think you are absolutely right. I don't think the will to approach the problem in the way you just described it exists today in the executive.

Mr. **Levitas**. I just want to make this observation in light of your comment, Mr. Roisman, before the last one.

In fairness to Dr. Karrh, even though it was not in his prepared testimony, Dr. Karrh did say he felt and the chemical manufacturers felt that it was necessary and proper and appropriate for EPA to go forward with Superfund to clean up the hazardous waste sites because of the potential for health effects down the line.

So just for the record, I want that to be clear in fairness to Dr. Karrh.

Dr. Rowland.

Mr. **Rowland**. Thank you, Mr. Chairman.

In response to Mr. Albosta's question about recommendations you would make to Congress about what could be done, you said that more study needs to be done by the Government and I certainly agree with that, much more study needs to be done by the Government and also by private companies, I think.

I think it ought to be a joint effort on the part of private companies and Government.

The point just made by Mr. Molinari about prevention is important, I think there has not been enough done in that area either.

Then you also said that victims' compensation laws needed to be enacted and you said that when there is objective damages, I believe, that that would be compensated.

My question is is there enough evidence now of objective damage so that compensation would be justified in some chemicals, and if so what are those chemicals?

Mr. ROISMAN. Your question and my statement to Mr. Albosta are slightly—I think we are talking about two slightly different things.

I want to clarify that before I answer the question.

My point about objective damage is those kinds of damages that people suffer that are directly quantifiable like medical bills and the like. I think your question is to causation, in other words, is the causation connection objective.

I don't feel qualified to give you a list of what those chemicals are and I think to some extent it may be that there is no list of the chemicals. When I talked to the medical doctors about toxic substances they have a general sense of what is a toxic substance but they tend to work from the patient back rather than from the substance forward.

If you have a patient, the patient has something that other people don't have, there is reliable evidence to show that the patient's damages could only have been caused by the exposure to the substance, then the substance is believed by the medical doctor to be the cause of the problem.

You have ruled out the other possibilities.

The doctor can then treat the patient by removing that source and comparable sources and actually seeing if the patient got better.

For some people it might be trichloroethylene, for others dioxin, for others it might be a chemical we have never thought could do that before.

I think it is very difficult. It is probably the case that for purposes of legislation you are going to have to put some parameters on. My guess is that you start with something like the list of hazardous substances now in the Superfund law. Put that kind of a parameter on it for lack of anything more concrete than that, I believe.

We don't have all the facts necessary to give the definitive list of health damaging chemicals in the country and then write a law to fit that.

My view is we shouldn't wait until we know them before we go ahead and provide a mechanism, a process by which if a particular person can prove that they have been damaged as a result of the exposure that they should be entitled to recovery.

Mr. ROWLAND. Reasonable doubt still exists then insofar as causation?

Mr. ROISMAN. Reasonable doubt exists in terms of the abstract question, which particular chemicals cause which illnesses? Among the scientific community of which Dr. Carnow is a member, I think individual analyses of individuals does not have that reasonable doubt in it.

Mr. **Rowland**. We talked about some variation in individuals that may be manifest in one whereas it is not in another. So there may be reasonable doubt.

Mr. **Roisman**. Well, it may be that as Mr. Albosta said one individual is affected differently. It doesn't mean as to the one affected that there are not competent medical experts who can—who are unable to say with confidence yes, this caused that.

So as to that individual I think again your question is can we indict a particular chemical. Can we say this chemical across-the-board will always hurt everybody if they are exposed to it at this level? I don't think we know that. We pass regulations based upon risk avoidance. But now we are dealing with a different question. It is not risk avoidance, it is causation and it is appropriate that it should be a different question.

Now we have a particular person, they come up and say, I have been exposed to this chemical and this is the level to which I have been exposed and look what happened to me. The doctor gets up and says I have examined you and it is the chemical that did it.

But should everyone be held to that level as a standard? The answer is no to the question of whether everybody should be subject to that level in order to recover.

Mr. **Albosta**. If I may, what happens if the defendent gets before the jury and the doctor says, "Yes, I think that the cancer or the pneumonia that this person has was caused by the toxic substance?"

But, on the other hand, the other person, the plaintiff says through their legal advice that, yes, but that is happening all the time, in fact, in the 1800's, before we had toxic substances, people were getting pneumonia.

How can you possibly boil this thing down to where you can say definitely that there is anything there in the exposure to the substance? Already we have two people, both exposed, one with the problem and one without a problem.

From your point of view, as a legal expert, how would you defend your person under those circumstances?

Mr. **Roisman**. Well, obviously, I would have my doctor testify much more than just what you have summarized and explain the basis for the doctor's conclusion that the exposure caused the particular illness.

I would cross-examine the defendent's expert to see whether the defendant's expert could really rebut those assumptions. I would not frame it as Dr. Rowland and I were discussing, in terms of whether everybody would have this effect if they got exposed.

I would focus it on that particular victim, did this victim get this from this particular exposure? If you are asking me, do I know that that always wins, no, no, it won't always win.

The legal system allows the person to lose when they should have won and to win when they should have lost, and we sort of have that built into the legal system, the process can still be "due" and therefore constitutionally permissible without always giving us truth.

The legal system gives us validity. I think the system is the best mechanism we have got for resolving the dispute. The other options, trial by combat, torture and so forth, I am not a proponent of.

Mr. **Albosta**. I yield to you.

Mr. **Rowland**. Would you say it would depend on how sharp one attorney is as opposed to another?

Mr. **Roisman**. I think it probably depends more on how good the expert is than the attorney.

Mr. **Rowland**. Or how well the attorney can bring out how good the expert is?

Mr. **Roisman**. You mean could the expert do it without the attorney? As a lawyer, I will say no, I think the attorney is at least a midwife to the case.

Mr. **Rowland**. I never looked at it that way, but thank you.

Mr. **Albosta**. Thank you.

Mr. **Levitas**. That last series of questions between Dr. Rowland and Mr. Roisman goes to the reaches of jurisprudence more so than this particular matter, although there could be relevance to it.
